Missile Defense Agency
a. Lead Agency: Missile Defense Organization

b. Preparing Agency: U.S. Army Space and Missile Defense Command

c. Cooperating Agencies: Federal Aviation Administration, Office of the Associate Administrator for Commercial Space Transportation

d. Proposed Action: Provide operationally realistic testing for GMD ETR.

e. Affected Jurisdictions: Kodiak Launch Complex, Kodiak Island Borough, Alaska; Vandenberg Air Force Base (AFB), Santa Barbara County, California; Reagan Test Site, United States Army Kwajalein Atoll; Pacific Missile Range Facility, Barking Sands, Kauai, Hawaii; Eareckson Air Station, Shemya Island, Alaska; Midway Atoll; King Salmon, Bristol Bay Borough, Alaska; Cordova, Valdez-Cordova Census Area, Alaska; Pillar Mountain, Kodiak Island Borough, Alaska; Pashagshak Point, Kodiak Island Borough, Alaska; Homer, Kenai Peninsula Borough, Alaska; Adak, Adak Island, Alaska; Pillar Point, San Mateo County, California; Wake Island, Oceania Atoll; Bremerton, Kitsap County, Washington; Pearl Harbor, Honolulu County, Hawaii; Port Hueneme/San Nicolas Island, Ventura County, California; Naval Station Everett, Snohomish County, Washington; Valdez, Valdez-Cordova Census Area, Alaska; Beale Air Force Base, Yuba County, California; Clear Air Force Station, Denali Borough, Alaska

f. Inquiries on this document may be directed to: U.S. Army Space and Missile Defense Command, ATTN: SMDC-EN-V (Ms. Julia Elliott), 106 Wynn Drive, Huntsville, AL 35805, by e-mail at gmdetreis@smdc.army.mil, or by phone at 1-800-823-8823.

g. Designation: Final Environmental Impact Statement

h. Distribution/Availability: DISTRIBUTION A. Approved for public release; distribution is unlimited.

i. Abstract: The Missile Defense Agency is proposing to develop the capability to conduct more realistic interceptor flight tests in support of GMD. The extension of the existing GMD test range would increase the realism of GMD testing by using multiple engagement scenarios, trajectories, geometries, distances, and speeds of target and interceptors that closely resemble those in which an operational system would be required to provide an effective defense. Extended range testing would include pre-launch activities, launch of targets and Ground-Based Interceptors from a number of widely separated locations, and missile intercepts over the Pacific Ocean. Target missiles would be launched from Vandenberg AFB, Kodiak Launch Complex, Pacific Missile Range Facility, Reagan Test Site (RTS), or from mobile platforms in the western Pacific Ocean. Interceptor missiles would be launched from Vandenberg AFB, Kodiak Launch Complex, or RTS. Dual target and interceptor missile launches would occur in some scenarios. Existing, modified, or new launch facilities and infrastructure would support these launch activities at the various locations.

Missile acquisition and tracking would be provided by existing test range sensors, ship-borne sensors, a Sea-Based Test X-Band Radar, and a mobile sensor (TPS-X) positioned at Vandenberg AFB, Kodiak Launch Complex, or RTS; and existing/upgraded radars at Beale AFB, California, Clear Air Force Station, and Eareckson Air Station, Alaska. In-Flight Interceptor Communications Data Terminals would be constructed near the proposed Ground-Based Interceptor launch sites. Commercial satellite communications terminals would be constructed at launch locations that do not have fiber optic communications links.

EXECUTIVE SUMMARY

ES1.1 INTRODUCTION

This Executive Summary includes Background, Purpose and Need for the Proposed Action, Proposed Action, Proposed Alternatives, Decision to be Made, Methodology of the Environmental Impact Statement (EIS), and Summary of Environmental Impacts. Tables ES-1 through ES-12 include an Impacts and Mitigations Summary for each location and for the No Action Alternative at all locations.

ES1.2 BACKGROUND

The National Environmental Policy Act (NEPA) of 1969 as amended (42 U.S. Code [USC] 4321, et seq.), the Council on Environmental Quality (CEQ) Regulations for Implementing the Procedural Provisions of NEPA (40 Code of Federal Regulations [CFR] 1500-1508), Department of Defense (DoD) Instruction 4715.9, Environmental Planning and Analysis, and the applicable Service environmental regulations that implement these laws and regulations, direct DoD officials to consider environmental consequences when authorizing and approving federal actions. Accordingly, this EIS examines the potential for impacts to the environment as a result of the proposed construction, operation, and test activities associated with the proposed Ground-Based Midcourse Defense (GMD) Extended Test Range (ETR). Under this Proposed Action, additional test facilities, including the Sea-Based Test X-Band Radar (SBX), test equipment, infrastructure, and communications links would be constructed and operated for the purpose of providing more realistic GMD flight testing in the North Pacific Region. Existing range facilities would be enhanced, and additional launch and support sites would be established to support more robust missile flight tests.

Within the DoD, the Missile Defense Agency (MDA) (formerly the Ballistic Missile Defense Organization) is responsible for developing and testing a conceptual Ballistic Missile Defense System (BMDS). There are three segments that make up the BMDS, Boost Phase Defense, Midcourse Defense, and Terminal Defense. Each segment of the BMDS is being developed to destroy an attacking missile in the corresponding boost, midcourse, or terminal phase of its flight. The boost phase is the portion of a missile’s flight in which it produces thrust to gain altitude and acceleration. This phase usually lasts between 3 to 5 minutes. The midcourse phase occurs outside much of the Earth’s atmosphere and the missile coasts in a ballistic trajectory. This phase can last as long as 20 minutes in the case of intercontinental ballistic missiles. During the terminal phase, the missile enters the lower atmosphere and continues on to its target. This phase lasts approximately 30 seconds. Each segment of the BMDS is composed of one or more elements, each of which consists of an integrated set of technology components, such as interceptors, radars, and communication links. GMD is one such element.
The GMD Joint Program Office, within the MDA, is responsible for overseeing the development of the GMD element. An operational GMD element architecture would include the five key components listed below and shown in figure ES-1.

- Ground-Based Interceptors (GBIs)
- X-Band Radar
- GMD Battle Management Command, Control, and Communications facilities and links
- Upgraded Early Warning Radars
- Space-Based Detection Capability

In July 2000, the MDA completed the National Missile Defense (NMD) Deployment EIS to support decisions concerning deployment of a GMD (formerly NMD) element. At the direction of the Secretary of Defense, however, the MDA re-focused the GMD element on operationally realistic testing under the concept of the GMD ETR. This EIS serves to analyze the proposed GMD ETR actions and alternatives for potential impacts on the environment.

On 17 December 2002, President George W. Bush announced plans to begin deployment of an initial set of missile defense capabilities by the year 2004. The deployment capability would be used in a defensive mode. This decision, however, is outside the scope of this document. Furthermore, the full scope and location of those assets are not yet ripe for NEPA analysis and will be the subject of future NEPA documentation, as appropriate. It is possible that some of those assets could share assets in common with some of those of the GMD ETR. Where further NEPA documentation is required, the limited deployment decision would examine any environmental impacts in its cumulative effects section, as applicable.

**ES1.3 PURPOSE AND NEED FOR THE PROPOSED ACTION**

The proliferation of weapons of mass destruction and long-range ballistic missile technology is increasing the threat to our national security. The GMD element would defend all 50 states against limited ballistic missile attack. The Secretary of Defense has identified the need to gain a higher level of confidence in the capability of the GMD to defend the United States through more robust interceptor flight tests under more realistic conditions.

The purpose of the Proposed Action is to provide for more realistic flight tests in support of development of the GMD element. The ETR would achieve this by providing additional target and interceptor launch locations, and sensors, in a wider range of intercept engagements and under more stressing conditions.

More realistic testing using trajectories and distances that closely resemble those required of an operational element is needed to ensure the GMD element being developed has the capability to defend the United States against limited missile attacks. To meet this need, the MDA proposes to gain a higher level of confidence in GMD’s capabilities to defend the United States through more robust system testing under more realistic conditions.

EXPLANATION
Note: Locations in this figure are for illustrative purposes only and are notional.

GMD Element Architecture

Not to Scale

Figure ES-1
Currently, the existing test ranges located in the Pacific Region and elsewhere are limited in their capabilities to provide for a geographically dispersed operational environment, suitable for GMD types of testing. As a result, current GMD element testing is constrained by how missile flight tests can be conducted, and in opportunities for multiple engagement scenarios.

**ES1.4 PROPOSED ACTION**

The Proposed Action is to construct and operate additional launch and test facilities including the SBX in the Pacific Region, and to conduct more realistic interceptor flight tests in support of GMD development. The extension of existing U.S. test ranges would increase the realism of GMD testing by using multiple engagement scenarios, trajectories, geometries, distances, and speeds of targets and interceptors that more closely resemble those for which an operational system would provide an effective defense. The GMD ETR testing would include pre-launch activities, launch of targets and GBIs from a number of widely separated locations, and missile intercepts over the Pacific Ocean. Potential GMD ETR test and test support locations are shown in figure ES-2.

For the purpose of this EIS, a flight test or test event represents a target missile flight, an interceptor missile flight, an intercept of a target missile, or a test of a sensor(s) independent of a missile flight test. Most tests would include the launch of a target missile; tracking by range and other land-based, sea-based, airborne, and space-based sensors; launch of an interceptor missile; target intercept; and debris impacting into broad open areas of the Pacific Ocean. Some test events proposed for later in the program would require multiple target and/or interceptor missile flights to validate GMD system performance. A total of approximately 10 launches per year is anticipated for the entire GMD ETR test program. For each of the alternatives, the proposed GMD ETR activities could include up to five missile launches (interceptors and/or targets) from a specific launch facility per year. The GMD ETR testing activities would likely occur over a period of approximately 10 years following a decision to proceed.

**ES1.5 PROPOSED ALTERNATIVES**

The alternatives for implementing the Proposed Action represent architectures for achieving more realistic interceptor flight tests in the Pacific Region. These architectures are organized around potential additional GBI missile launch sites, with other new and existing test components being located to provide maximum test effectiveness. For analysis purposes in this EIS, three alternative test architectures have been identified based on developing additional missile launch capability at (1) Kodiak Launch Complex (KLC), Alaska; (2) Vandenberg Air Force Base (AFB), California; and (3) both KLC and Vandenberg AFB. Target missiles launched as a part of this ETR program would originate from KLC; Vandenberg AFB; Pacific Missile Range Facility (PMRF), Hawaii; Reagan Test Site, Kwajalein Atoll; or from a mobile air or sea launch platform in the Pacific region. All missile intercepts would occur over the Pacific Ocean. Each alternative would include common GMD test components consisting of GBIs, target missiles, In-Flight Interceptor Communication System Data Terminals (IDT), the SBX, and other sensors and instrumentation.
Although Midway was an alternative site in the Draft EIS, MDA has determined that it is no longer a reasonable alternative and will not be a proposed site for ETR activities. The IDT on-board the SBX would perform the function that had been planned for Midway. The discussion of Midway has been retained in the Final EIS, however, in order to preserve the work that has already been performed.

---

**Potential GMD ETR Test and Test Support Locations**

**Pacific Ocean**

**Figure ES-2**
ES1.6 **NO ACTION ALTERNATIVE**

Under the MDA No Action Alternative, the GMD ETR would not be established, and additional facilities and components to be used in ETR operations would not be built. Existing launch sites and test range activities, however, would continue at the various locations, including support of ongoing GMD test activities. The Federal Aviation Administration (FAA) also has a No Action Alternative related to this EIS, as described below.

ES1.7 **DECISION TO BE MADE**

The initial decision to be made by the MDA is whether to implement the Proposed Action to construct and operate additional GMD test facilities, infrastructure, and communication links to enable the MDA to conduct enhanced GBI flight testing; or to choose the No Action Alternative. If the MDA selects the Proposed Action, then a second decision would be made as to which of the three alternative interceptor launch scenarios and locations would most effectively meet the objectives of the enhanced test program.

The FAA, which is a cooperating agency for this EIS, will also rely on this analysis to make its licensing decisions for the KLC. The FAA, Office of the Associate Administrator for Commercial Space Transportation, is a cooperating agency because of its regulatory authority in licensing the operation of KLC, as defined in 49 USC Subtitle IX—Commercial Space Launch Activities, 49 USC 70101-70121 and supporting regulations. The FAA has special expertise and legal responsibility related to the licensing of commercial launch facilities. The FAA is responsible for providing oversight and coordination for licensed launches and protecting the public health and safety, safety of property, and national security and foreign policy interests of the United States. Licensing of launches and reentries, operating a launch or reentry site, or some combination, is considered a federal action for which environmental impacts must be considered as part of the decision making process as required by NEPA.

Alaska Aerospace Development Corporation (AADC) applied for and was granted a launch site operator license for the operation of KLC in September 1998. A license to operate a launch site remains in effect for 5 years from the date of issuance unless surrendered, suspended, or revoked before the expiration of the term and is renewable upon application by the licensee (14 CFR 420.43). The existing FAA license for the operation of KLC will expire in September 2003.

Should the FAA not reissue a launch site operator's license for KLC to conduct launches, the MDA would be required to choose an alternative that does not include KLC. KLC is the only launch complex evaluated in the EIS that requires a license from the FAA.

An environmental review is just one component of the FAA’s licensing process. FAA Order 1050.1D (*Policies and Procedures for Considering Environmental Impacts*) describes the Agency’s procedures for implementing NEPA. Specifically, it requires that the FAA decision making process facilitate public involvement by including consideration of the effects of the Proposed Action and alternatives; avoidance or minimization of adverse effects attributable to
the Proposed Action; restoration and enhancement of resources, and environmental quality of
the nation. These requirements will be considered in the FAA’s licensing decision.

In addition to the environmental review and determination, applicants must complete a policy
review and approval, safety review and approval, payload review and determination, and a
financial responsibility determination. The purpose of the Policy Review and Approval process
is to determine whether or not the information in the license application presents any issues
affecting U.S. national security or foreign policy interests, or international obligations of the
United States. The purpose of the Safety Review and Approval process is to determine whether
an applicant can safely conduct the launch of the proposed launch vehicle(s) and any payload.
The purpose of the Payload Review and Determination is to determine whether a license
applicant or payload owner or operator has obtained all required licenses, authorization, and
permits. The purpose of the Financial Responsibility Determination is to ensure that all
commercial licensees demonstrate financial responsibility to compensate for the maximum
probable loss from claims by a third party for death, bodily injury, or property damage or loss
resulting from an activity carried out under the license; and the U.S. Government against a
person for damage or loss to government property resulting from an activity carried out under
the license. All of these reviews, including the environmental review, must be completed prior to
issuing a license. All FAA safety analyses would be conducted separately and would be
included in the terms and conditions of the license.

A license to operate a launch site authorizes a licensee to offer its launch site to a launch
operator for each launch point for the type and weight class of launch vehicle identified in the
license application and upon which the licensing determination is based. Issuance of a license
to operate a launch site does not relieve a licensee of its obligation to comply with any other
laws or regulations, nor does it confer any proprietary, property, or exclusive right in the use of
airspace or outer space (14 CFR 420.41).

ES1.8 SCOPE OF THE ENVIRONMENTAL IMPACT STATEMENT

The GMD testing would be of two types: (1) validation of the GMD operational concept and (2)
more robust GMD element testing. The facilities and operations to validate the GMD
operational concept, and improve the realism of GMD element testing, are each a part of the
GMD Test Bed. Each part of the test bed, however, serves a different test function and has
independent utility, purpose, and need. The independent parts of the test bed also have
different implementation schedules. Consequently, the independent parts of the test bed are
being evaluated in separate NEPA analyses. Validation of the operational concept is analyzed
in the GMD Validation of Operational Concept Environmental Assessment (EA). These actions
are designed to validate potential non-launch activities associated with the GMD operational
concept by testing the interoperability of the GMD components in a realistic environment. The
EA analyzed construction, testing, and support activities at Fort Greely, Clear Air Force Station,
and Eielson AFB in central Alaska; Eareckson Air Station on Shemya, Alaska; and Beale AFB,
California.

The second type of GMD testing, which is analyzed in this EIS, would involve more robust
interceptor flight tests with participation of other GMD components such as an SBX and IDTs to
achieve more realistic testing. This enhanced ETR flight testing would be accomplished through
the extension of existing Pacific Region test range areas that are currently supporting GMD test activities. By extending these test range areas, the realism of GMD testing would be increased through the use of multiple missile engagement scenarios, trajectories, geometries, distances, and speeds of targets and interceptors that more closely resemble those for which an operational system would provide an effective defense. Most tests would include the launch of a target missile; tracking by range and other land-based, sea-based, airborne, and space-based sensors; launch of a GBI; and missile intercepts at high altitudes over the Pacific Ocean. Some test events proposed for later in the program would require multiple target and interceptor missile flights to validate GMD element performance.

ES1.9 SCOPING PROCESS

The CEQ Regulations implementing NEPA require an open process for determining the scope of issues related to the Proposed Action and its alternatives. Comments and questions received, as a result of this process, assist the DoD in identifying potential concerns and environmental impacts to the human and natural environment.

The GMD ETR EIS public scoping period began on 28 March 2002, when the Notice of Intent to prepare an EIS was published in the Federal Register. The scoping comment period was originally scheduled to end on 10 May 2002, but was extended to 20 May 2002 in response to public request. Subsequently, inclusion of the SBX in the EIS analysis extended scoping and the comment period even further, through 20 December 2002.

A number of methods were used to inform the public about the GMD ETR Program and of the locations of the scheduled scoping meetings. These included:

- The Notice of Intent announcement in the Federal Register
- Paid advertisements in local and regional newspapers

Public scoping meetings were held at eight locations where communities could be affected by the GMD ETR program. During these public scoping meetings, attendees were invited to ask questions and make comments to the program representatives at each meeting. In addition, written comments were received from the public and regulatory agencies at the scoping meeting, and by letter and e-mail during the extended comment period. Comments received from the public and agencies pertaining to specific resource areas and locations were considered, and more detailed analysis provided in the EIS. Those comments received from the public concerning DoD policy and program issues are outside the scope of what is required to be analyzed in an EIS.
ES1.10 SUMMARY OF THE DRAFT ENVIRONMENTAL IMPACT STATEMENT PUBLIC REVIEW PROCESS

The public review and comment period began with the publication of a Notice of Availability (NOA) for the GMD ETR Draft EIS, published in the Federal Register on Friday, 7 February 2003, by the MDA and the FAA. This initiated a review period for the public and interested agencies to review the Draft EIS and submit their comments. Copies of the Draft EIS were made available for review on the MDA web site and in local libraries in the areas affected and were provided to those who requested a copy of the EIS.

In addition to the Draft EIS review process, seven public hearings were held from 24 February 2003 to 6 March 2003. Detailed information on locations and times for each of the public hearings was published in local and regional newspapers 2 weeks in advance, and public-service announcements and press releases were provided to radio and television stations. A total of 255 people attended the public hearings. Chapter 8.0 of the EIS contains a reproduction of all comments and responses to those comments. Comment sources include transcripts of the public hearings, oral comments, electronic mail, and written comments.

ES1.11 METHODOLOGY OF THE ENVIRONMENTAL IMPACT STATEMENT

To assess the significance of any impact, a list of activities necessary to accomplish the Proposed Action was developed. The affected environment at all applicable locations was then described. Next, those activities with the potential for environmental consequences were identified.

Fourteen broad areas of environmental consideration were considered to provide a context for understanding the potential effects of the Proposed Action and to provide a basis for assessing the severity of potential impacts. These areas included air quality, airspace, biological resources, cultural resources, geology and soils, hazardous materials and hazardous waste, health and safety, land use, noise, socioeconomics, transportation, utilities, visual and aesthetic resources, and water resources. Subsistence resources were also considered for potential sites in Alaska. Environmental justice is discussed separately.

ES1.12 SUMMARY OF ENVIRONMENTAL IMPACTS

This section summarizes the conclusions of the analyses made for each of the areas of environmental consideration based on the application of the described methodology. Only those activities for which a potential environmental concern was determined at each candidate location are described for the No Action Alternative and Alternatives 1, 2, and 3. Tables ES-1 through ES-12 include a description of all potential impacts and mitigation measures.
ES1.12.1 NO ACTION ALTERNATIVE

Kodiak Launch Complex

Land Use
AADC applied for and was granted a launch site operator license for the operation of KLC in September 1998. A license to operate a launch site remains in effect for 5 years from the date of issuance unless surrendered, suspended, or revoked before the expiration of the term and is renewable upon application by the licensee (14 CFR 420.43). The existing FAA license for the operation of KLC will expire in September 2003.

If the FAA renews the launch site operator’s license, the AADC would continue launching various commercial and military launch vehicles from KLC. The current operating license allows up to nine launches per year. However, AADC has estimated that approximately five missiles would be launched per year from KLC.

After September 2003, the FAA’s No Action Alternative would be the nonrenewal of the AADC’s launch site operator license that permits them to operate KLC for the purposes of conducting launches. KLC would no longer be licensed by the FAA to conduct launches. In the absence of any other arrangement, launch activity at KLC would be discontinued. The AADC currently holds a 30-year renewable interagency land management assignment from the Alaska Division of Land. If launch activity were discontinued at KLC, AADC would coordinate with the state to determine a proposed future use for the land. The facilities and equipment at the site could be used for other government purposes or handled as government surplus (e.g., sold). The lands on Kodiak Island at Narrow Cape have previously been considered for other development activities such as prisons, schools, and other facilities. The site is located on one of the few improved roads on the Island, and may be available for development for other purposes if AADC were no longer licensed to conduct launches.

ES1.12.2 PROPOSED ACTION ALTERNATIVE 1

Kodiak Launch Complex

Air Quality
There would be an increase in air pollutant emissions from construction of the GBI, target, IDT, and sensor elements of the GMD ETR at KLC. The majority of the ground disturbance would be completed in approximately 15 months. Construction emissions vary from day to day and activity to activity, with each activity having its own potential to release emissions. Because of the variability in timing and intensity of construction, estimating construction-phase pollutant emissions is difficult. Nevertheless, it is assumed that there would be particulate matter with an aerodynamic diameter of less than or equal to 10 micrometers (PM-10), impacts from ground disturbance and other pollutants (carbon monoxide, oxides of nitrogen, volatile organic compounds, and oxides of sulfur) primarily emitted from construction equipment exhaust and construction worker commuting. Once construction ceased, air quality would return to its former level.

The de minimis thresholds are federal limits listed in 40 CFR 51.583(b)(1). Federal actions with emissions below the de minimis levels are presumed to conform, that is, not cause or contribute to new violations of National Ambient Air Quality Standards (NAAQS), in areas that are in non-attainment. For the least severe nonattainment areas, the de minimis level for each criteria
pollutant (and their precursors, in the case of ozone) is 90.7 metric tons (100 tons) per year. Construction emission levels at KLC would be well below the *de minimis* levels, and since the area is currently in attainment for all federal standards, it is anticipated that the proposed construction and commuting emissions would not cause exceedances of the NAAQS or Alaska Ambient Air Quality Standards (AAQS) and would not have a long-term impact to air quality in the area.

The yearly generator and commuting emissions from the Proposed Action would also be below the 90.7-metric-ton (100-ton) per year criteria pollutant federal *de minimis* levels that would apply to a non-attainment area. As KLC is in attainment for all criteria pollutants, it is anticipated that the proposed commuting and generator operations would not cause exceedances of the NAAQS or Alaska AAQS. Use of these generators would however require an amendment to the existing Pre-approved Limit Permit for KLC.

The primary exhaust products of the GBI booster are hydrogen chloride, aluminum oxide, chlorine, carbon monoxide, carbon dioxide, hydrogen, nitrogen, oxygen, and water. The federal *de minimis* threshold limits were used to compare oxides of nitrogen and carbon monoxide. In the event the 5 GBIs were launched in a year, the conservatively estimated annual emissions for oxides of nitrogen were determined to be 31.8 tons, below the 100 tons standard. Carbon monoxide was calculated at 5.4 tons for 5 launches, which is well below the 100 tons annual standard. Dual target and dual GBI launches were analyzed using the Open Burn/Open Detonation Dispersion Model to determine exhaust emissions of aluminum oxide, hydrogen chloride, and carbon monoxide. The results of the modeling show that concentrations produced by dual launches of a GBI would remain within NAAQS, Alaska AAQS, and U.S. Air Force standards. The results of modeling a dual Peacekeeper target show that the level of hydrogen chloride would be below the 1-hour Air Force standard, but would exceed the peak hydrogen chloride standard for a short duration. Other emissions were determined to be within NAAQS and Alaska AAQS standards. The nominal launch of a single Peacekeeper Target is anticipated to remain within NAAQS, Alaska AAQS, and Air Force standards as fewer emissions would be released with a single launch.

The KLC EA indicated no significant impacts to air quality as a result of nine annual launches and that impacts would not accumulate with multiple launches. It is not likely that the Proposed Action of up to five launches (GBI and target) in conjunction with other currently planned or anticipated launches at KLC would exceed nine launches per year. Overall impacts to regional air quality are not expected to be adverse and would remain within NAAQS and state AAQS. Due to the limited industrialization of Kodiak Island and the surrounding environment, the potential cumulative impacts to air quality due to the proposed interceptor and target facility construction and launches would not be substantial.

**Biological Resources**

No significant impacts to vegetation are anticipated, since new GBI, target, IDT, and sensor-related construction activities would occur mainly in upland areas of hairgrass-mixed forb meadow, one of the predominant vegetation types at KLC. This loss of vegetation (approximately 26 hectares [64.2 acres]) would represent less than two percent of the total vegetation available within KLC boundaries. No federally proposed or listed candidate, threatened, or endangered species are located within the boundaries of KLC. The Steller sea lion (*Eumetopias jubatus*) population near Kodiak Island was included in the population classified as endangered in 1997. The closest Steller sea lion haulout area, approximately 5
kilometers (3 miles) away on Ugak Island, would not be affected by site preparation noise. No Steller sea lion rookeries have been identified in the ROI.

Federally threatened Steller’s eiders and endangered short-tailed albatross offshore would also be outside the range of site preparation noise levels and are not anticipated to be affected. Construction of the GBI launch silos and perimeter fencing around the launch area could disturb approximately 0.6 hectare (1.6 acres) of palustrine, emergent, persistent, seasonally flooded wetlands and 0.2 hectare (0.4 acre) of palustrine, scrub/shrub, broad-leaved deciduous, saturated wetlands. Indirect disturbance to wetlands would be minimized by implementing appropriate AADC Best Management Practices for soil erosion control to control runoff. Normal GBI and target launch activities are not expected to significantly impact vegetation. Disturbance to wildlife from the GBI and target launches would be brief and is not expected to have a lasting impact nor a measurable negative effect. The proposed missile launches would be infrequent, up to five per year over a period of 10 years.

**Hazardous Materials and Hazardous Waste**

The construction of the GBI, target, IDT, and sensor-related facilities would use construction-related hazardous materials. The hazardous materials that are expected to be used are common to construction activities and may include diesel fuel, anti-freeze, hydraulic fluid, lubricating oils, welding gases, and small amounts of paints, thinners, and adhesives.

Hazardous materials management techniques would be used during the construction period to minimize the amount of hazardous materials stored, the threat of their accidental and unplanned release into the environment, and the quantity of hazardous waste generated. Therefore, substantial impacts to the environment are not expected from the presence of potentially hazardous materials and the generation of wastes during the proposed action construction activities. Missile components would be transported to KLC for temporary storage, pre-launch assembly and checkout, and launch preparation in accordance with Department of Transportation (DOT) requirements. The hazardous materials contained within the missiles include solid propellant for the missile boosters and a form of monomethyl hydrazine liquid fuel and nitrogen tetroxide oxidizer for the GBI Exoatmospheric Kill Vehicle. No onsite fueling of the GBI would occur; therefore, the likelihood of release and environmental effect would be small. Small amounts of potentially hazardous and non-hazardous wastes are expected to be generated during launch operations. Wastes would be segregated as nonhazardous, hazardous, and possibly special wastes for collection and disposal in accordance with applicable state and federal requirements. Hazardous waste would be containerized and properly disposed of by individual contractors in accordance with Alaska Administrative Code, Title 18 - Environmental Conservation, Chapter 16 and KLC requirements. Only licensed hazardous waste transporters would transport hazardous wastes offsite. No permitted hazardous waste treatment or disposal facilities exist on Kodiak Island, therefore, all hazardous waste would be transferred by licensed hazardous waste transporters to the mainland for appropriate treatment or disposal.

The volume of nonhazardous, construction generated waste is expected to be small based on past experience. Nonhazardous waste would be removed by individual contractors for appropriate disposal at the Kodiak Island Borough landfill or at a landfill on the Alaska mainland.
Health and Safety

All new construction or structure modification would be accomplished using the same procedures that AADC used to construct the present KLC infrastructure. Restricted public access to the immediate construction site would be ensured through use of signs and fencing. A health and safety plan would be prepared by the contractor and submitted to AADC to ensure the health and safety of onsite workers.

Prelaunch activities would include transportation of boosters, liquid fuel, and liquid oxidizer tanks for the Exoatmospheric Kill Vehicle and missile preparation, assembly, and integration testing. All components and equipment would be handled and shipped in accordance with applicable military, state, and DOT regulations. Missile components would be packaged in shipping containers designed according to Alaska, DOT, and military requirements for protection of missile components and reduction of fire/explosion or risk of hazardous materials release in the event of an accident. The boosters would be processed and prepared for launch in the same manner as previous and ongoing missile launches from KLC. The major system components (boosters, in-flight destruct package, range safety equipment and missile instrumentation) would be assembled and tested in the Integration and Processing Facility. All preparation activities would be conducted in accordance with applicable safety regulations and operations plans.

Before each launch at KLC, the Range Integrator and the KLC Safety Officer must approve all flight plans, trajectories, and planned impact areas. The KLC Safety Officer would issue range clearance and surveillance for the Launch Hazard Area and flight safety corridor. The KLC Safety Officer would establish the safety zones around the launch site and along the missile flight path no less than 4 hours before each launch. Official notifications to airmen and mariners would be used to identify the areas to be cleared. The KLC Safety Officer would then ensure the safety zone is verified clear of non-mission essential personnel and vessels out to the territorial limit approximately 20 minutes before launch.

Water Resources

AADC Best Management Practices and other standard operating procedures would be used during construction and operational activities to minimize erosion and other types of impacts that could reduce the quality of affected water resources. Standard operating procedures related to the handling, disposal, recycling, and other use of hazardous materials and wastes would be followed, including spill prevention, containment, and control measures while transporting equipment and materials. The GBI and Target missiles launched from KLC would disperse certain exhaust emission products over a large area. The primary emission products of concern from a water quality-standpoint are hydrogen chloride and aluminum oxide. These emissions are not expected to cause a significant water quality impact. Environmental monitoring was required as part of the KLC launch site operator license and called for the monitoring of at least the first five launches from KLC. As summarized in Summary Findings of KLC Environmental Monitoring Studies 1998-2001, water quality sampling and analysis indicate there have been no discernable effects on water chemistry from KLC launches to date. Water quality was sampled before and after KLC launches, including pH level, total aluminum, and perchlorate concentration (U.S. Environmental Protection Agency method 314.0 for water).
Vandenberg Air Force Base

Air Quality
The proposed target missiles would contain less solid rocket fuel capacity than previously analyzed Titan IV, Delta II, Atlas V, and Delta IV missiles; therefore, it is anticipated they would produce lower exhaust emissions. Dual Peacekeeper target launches were analyzed using the Open Burn/Open Detonation Dispersion Model to determine exhaust emissions of aluminum oxide, hydrogen chloride, and carbon monoxide. The results of the modeling show that the level of hydrogen chloride would be below the 1-hour Air Force standard, but would exceed the peak hydrogen chloride standard for a short duration. Emission levels for both carbon monoxide and aluminum oxide were determined to be within NAAQS and California AAQS. The nominal launch of a single Peacekeeper Target is anticipated to remain within NAAQS, California AAQS, and Air Force standards as fewer emissions would be released with a single launch.

The *de minimis* thresholds are federal limits listed in 40 CFR 51.583(b)(1). Federal actions with emissions below the *de minimis* levels are presumed to conform, that is, not cause or contribute to new violations of NAAQS, in areas that are in non-attainment. For the Vandenberg AFB area, the *de minimis* levels for volatile organic compounds and nitrogen oxide are 45 metric tons (50 tons) per year, and the levels for carbon monoxide, oxides of sulfur, and PM-10 are 90.7 metric tons (100 tons). In the event that five Peacekeeper Targets are launched in a year, the conservatively estimated annual emissions for oxides of nitrogen would total 18.3 metric tons (20.2 tons), below the 45-metric-ton (50-ton) limit. Carbon monoxide was calculated to be 48.8 metric tons (53.8 tons), also below the federal limit of 90.7 metric tons (100 tons).

Previous modeling performed in the Supplemental EELV EIS, analyzed the Delta IV, a slightly larger launch vehicle than the proposed Peacekeeper Target. In the EELV EIS, predicted levels of carbon monoxide and oxides of nitrogen for the Delta IV were determined to be within the NAAQS and California AAQS acceptable levels. It is anticipated that the proposed Peacekeeper Target would also be within the NAAQS and California AAQS.

The review of the proposed action as required by the General Conformity Rule resulted in a finding of presumed conformity to the State Implementation Plan. Total foreseeable direct and indirect emissions caused by the proposed action would be both less than the mandated *de minimis* thresholds and less than 10 percent of the established Santa Barbara County Air Pollution Control District (SBCAPCD) budget. The Determination of Non-Applicability is included as appendix J of the EIS.

Biological Resources
Minor modifications to existing launch facilities would result in little to no ground disturbance, minimizing impacts to vegetation. Launch exhaust products would include hydrogen chloride, aluminum oxide, carbon monoxide, nitrogen dioxide, carbon dioxide, water, and chlorine. Nominal launch activities during dry conditions could result in the deposition of very small amounts of aluminum oxide from missile exhaust. Most of the aluminum oxide would be suspended in air and dispersed over extremely large areas; the amount deposited in surface waters would have no adverse effect. The primary potential for impacts to wildlife would be from the noise created during the proposed missile launches. Disturbance to wildlife from the launches would be brief and is not expected to have a lasting impact nor a measurable negative effect on migratory bird populations. Waterfowl would quickly resume feeding and other normal behavior patterns after a launch is completed.
Cultural Resources
Minor modifications to existing launch facilities would result in little to no ground disturbance. Potential effects could result from this debris striking the ground where surface or subsurface archaeological deposits or other cultural resources are located resulting in soil contamination, fire, and/or resource damage, which would all require a reparation effort. These efforts would be coordinated with applicable range representatives and agencies to develop appropriate mitigation measures to avoid impact to sensitive resources and to restore natural areas as necessary.

Several of the facilities proposed for refurbishment and reuse are eligible for listing on the National Register of Historic Places. Prior to the reuse of these facilities, consultation would occur with the State Historic Preservation Officer to ensure the protection of, or appropriate mitigation for these facilities.

Land Use
Maximum use would be made of Vandenberg AFB’s existing infrastructure and facilities. Minor facility modifications would be necessary under this alternative. Activities would be accomplished at an existing locale for such use and would not produce an adverse impact involving land use.

Planning and execution of launches would be in compliance with federal, state, local, and range land use requirements. Proposed activities would be compatible with the coastal consistency requirements. Closures of recreational areas and adjacent parks would continue during periods of hazardous operation. To minimize potential land use conflicts, coastline, beach, and recreational area availability would continue to be made known to the public through various local media sources.

Pearl Harbor, Reagan Test Site, Port Hueneme, Naval Station Everett, Port Adak, Port of Valdez
Potential impacts of SBX operations at these locations would be similar as described below, and would apply to Alternatives 1, 2, and 3.

Airspace, Health and Safety
Unrestricted operation of the SBX at the mooring location would have the potential to adversely affect air operations. However, in order to avoid or minimize adverse effects from electromagnetic radiation/electromagnetic interference, DoD has established a coordination process with responsible agencies and airspace users. A full electromagnetic radiation/electromagnetic interference survey and analysis is being conducted by the Joint Spectrum Center, in coordination with the FAA, DOT, and other potentially affected users. The survey would be used in preparing a DD Form 1494 (Application for Equipment Frequency Allocation) that is required as part of the spectrum certification and frequency allocation process. The completed DD Form 1494 that has been processed and approved by the appropriate national and international authorities would be required prior to SBX testing. The results of the survey would also be used to define the safe operating area for the SBX (acceptable azimuths and operating angles). This operating area would not interfere with airspace operations and would allow for a safe operating environment.
ES1.12.3 PROPOSED ACTION ALTERNATIVE 2

Kodiak Launch Complex

Air Quality, Biological Resources, Hazardous Material and Hazardous Wastes, Health and Safety, and Water Resources

Impacts would be similar to Alternative 1, with approximately 25 percent less area disturbed during construction. There would be no construction or operations related to GBI launches and their associated support equipment including IDT.

Vandenberg Air Force Base

Air Quality

Under Alternative 2, GBI and target missiles would be launched from Vandenberg AFB. The GBI exhaust emissions are approximately one third as much as the Peacekeeper emissions. Impacts from GBI launches would therefore be similar to but less than those described for Alternative 1.

IDT construction would disturb approximately 5.9 hectares (14.6 acres) and would last approximately 7 months. Emissions would include PM-10 from ground disturbance and other pollutants (carbon monoxide, oxides of nitrogen, volatile organic compounds, and oxides of sulfur) primarily emitted from construction equipment exhaust and construction worker commuting. As Vandenberg AFB is within a non-attainment area for the California AAQS 1-hour ozone standard, exhaust emissions of nitrogen oxides and hydrocarbons would be of concern. For the Vandenberg AFB area, the de minimis levels for volatile organic compounds and nitrogen oxide are 45 metric tons (50 tons) per year, and the levels for carbon monoxide, oxides of sulfur, and PM-10 are 90.7 metric tons (100 tons). IDT construction and worker commuting emissions would be much less than these de minimis levels. Emissions would be monitored in accordance with Memorandum of Agreements between Vandenberg AFB and Santa Barbara County Air Pollution Control District.

The review of the proposed action as required by the General Conformity Rule resulted in a finding of presumed conformity to the State Implementation Plan. Total foreseeable direct and indirect emissions caused by the proposed action would be both less than the mandated de minimis thresholds and less than 10 percent of the established SBCAPCD budget. The Determination of Non-Applicability is included as appendix J of the EIS.

Biological Resources

Impacts would be similar to those described for Alternative 1; however, facility modifications would also include GBI facilities. Other impacts would be as described for Alternative 1.

Cultural Resources

Construction would include minor modifications to existing facilities and construction of an IDT. Several of the facilities proposed for refurbishment and reuse are eligible for inclusion on the National Register of Historic Places. Prior to the reuse of these facilities, consultation would occur with the State Historic Preservation Officer to ensure the protection of, or appropriate mitigation for these facilities. After selection of an IDT site from the six alternative locations, records on file at Vandenberg AFB would be consulted to determine whether cultural sites have been identified at this location. Should cultural resources be found during the course of any
GMD ETR activity, all activities would cease in the area and the proper authorities would be notified. Subsequent actions would follow the guidance provided. The GMD Project Office would be responsible for implementation of any cultural resources avoidance or mitigation measures assigned to this project as a condition of approval for proceeding with any proposed activity.

Flight activity impacts would be similar to those described for Alternative 1.

Land Use
Impacts would be as described for Alternative 1. Proposed activities would be in accordance with coastal consistency requirements.

Water Resources
Construction of an IDT under Alternative 2 would disturb approximately 5.9 hectares (14.6 acres) at Vandenberg AFB. Construction projects that disturb 1 acre or greater require a Construction Activities Storm Water General Permit from the California State Water Resources Control Board, or its local Central Coast Regional Water Quality Control Board. A related Stormwater Pollution Prevention Plan would also need to be prepared before the commencement of any soil-disturbing activities. All appropriate water quality-related Best Management Practices would be followed during construction, and related water quality impacts would not be significant. Operation of the IDT would not cause water quality impacts and potable water supplies are sufficient to handle the minor increase in potable water demand.

ES1.12.4 PROPOSED ACTION ALTERNATIVE 3
Potential environmental impacts of activities in Alternative 3 would be as described for Alternatives 1 and 2. This would include GBI launches from KLC, Reagan Test Site, and Vandenberg AFB, and construction or modification of the required support facilities for dual launches of GBI and target missiles at each location. Impacts described below for the Broad Ocean Area would also apply to Alternatives 1 and 2.

Broad Ocean Area
Airspace
After launch, typically the GBI and target missiles would be above 18,290 meters (60,000 feet) within seconds of launch. As such, all other local flight activities would occur at sufficient distance and altitude that the target missile and GBI missiles would be little noticed. However, activation of stationary altitude reservation procedures, where the FAA provides separation between non-participating aircraft and the missile flight test activities, would impact the controlled airspace available for use by non-participating aircraft for the duration of the altitude reservation, usually for a matter of a few hours, with a backup day reserved for the same hours. Because the airspace in most of the intercept debris areas is not heavily used by commercial aircraft, and is far removed from the en route airways and jet routes crossing the North Pacific, the impacts to controlled/uncontrolled airspace would be minimal. However, the intercept scenarios with targets from KLC and GBIs from Vandenberg AFB may have moderate impacts to airspace due to the potential impacts from intercept debris.
The Range Commanders Council has been determined that intercept debris as small as 1 gram could cause significant damage to a commercial aircraft traveling at cruising speed and altitude. The debris cloud is approximately 35 kilometers (22 miles) in diameter, and the area where the probability of fatality is greater than one in one million is approximately 22 kilometers (13.6 miles) in diameter. This area of higher risk would need to be avoided by all aircraft. The time for the intercept debris to pass through commercial airspace cruising altitudes is approximately 3 hours after the intercept. All en route airways and jet routes that are predicted to pass through the missile intercept debris areas would need to be identified before a test to allow sufficient coordination with the FAA to determine if the aircraft on those routes would be affected, and if so, if they would need to be re-routed or rescheduled. Routing around the debris areas would be handled in a manner similar to severe weather. The additional time for commercial aircraft to avoid the area would generally be less than 5 minutes at cruising altitudes and speeds.

**Biological Resources**

Of particular concern is the potential for impacts to marine mammals from both acoustic and non-acoustic effects. Potential acoustic effects include behavioral disturbance (including displacement), acoustic masking (elevated noise levels that drown out other noise sources), and (with very strong sounds) temporary or permanent hearing impairment. Potential non-acoustic effects include physical impact by falling debris, entanglement in debris, and contact with or ingestion of debris or hazardous materials. The missiles could generate a sonic boom upon launch or reentry. Each missile would propagate a unique sonic boom contour depending upon its mass, shape, velocity, and reentry angle, among other variables. The location of the possible impact point would vary depending upon the particular flight test profile. It is therefore difficult to produce the specific location, extent, duration, or intensity of sonic boom impacts upon marine life. These noise levels would be of very short duration. The first-, second-, and third-stage target missile boosters and the target vehicle’s payload, which all fall to the ocean surface, would impart a considerable amount of kinetic energy to the ocean water upon impact. Missiles and targets would hit the water with speeds of 91 to 914 meters (300 to 3,000 feet) per second. At close ranges, injuries to internal organs and tissues would likely result. However, injury to any marine mammal by direct impact or shock wave impact would be extremely remote (less than 0.0006 marine mammals exposed per year).

Debris impact and booster drops in the Broad Ocean Area could occur within the 322-kilometer (200-mile) limit of the Exclusive Economic Zone of affected islands. The natural buffering capacity of seawater and the strong ocean currents would neutralize reaction to any release of the small amount of liquid propellant contained within the Divert and Attitude Control System or Liquid Propellant Missile. Analysis in the *Marine Mammal Technical Report*, prepared in support of the Point Mugu Sea Range EIS, determined that there is a very low probability that a marine mammal would be killed by falling missile boosters, targets, or debris as a result of tests at the Point Mugu Sea Range (less than 0.0149 marine mammals exposed per year). The potential for an object or objects dropping from the air to affect marine mammals or other marine biological resources is less than $10^{-6}$ (1 in 1 million). The probability of a spent missile landing on a cetacean or other marine mammal is remote.
This probability calculation was based on the size of the area studied and the density of the marine mammal population in that area. The analysis concluded that the effect of this missile debris and intact missiles coming down in the open ocean would be negligible. The range area at Point Mugu is smaller (93,200 square kilometers [27,183 square nautical miles]) than the PMRF range area (144,000 square kilometers [42,000 square nautical miles]) and other open ocean areas proposed for intercepts, and the density of marine mammals in the Point Mugu Sea Range is larger than the density found in PMRF range area and the open ocean. It is reasonable to conclude that the probability of a marine mammal being injured or killed by missile or debris impact from U.S. Navy testing at PMRF and other locations in the open ocean is even more remote than at Point Mugu, since the area at PMRF is larger and the density of marine mammals is smaller. Following formal consultation, the National Marine Fisheries Service concluded that the Proposed Action is not likely to adversely affect any marine mammal species.

<tr>
<td><strong>Air Quality</strong></td>
<td>A minimal increase in air emissions from construction would not affect the region’s current attainment status. The results of modeling to determine exhaust emissions of aluminum oxide, hydrogen chloride, and carbon monoxide show that concentrations produced by dual launches of a Ground-Based Interceptor would remain within National Ambient Air Quality Standards (NAAQS), California Ambient Air Quality Standards (AAQS), and U.S. Air Force standards. Significant air quality impacts due to Ground-Based Interceptor launches are not anticipated.</td>
<td>A minimal increase in air emissions from target construction would not affect the region’s current attainment status. The results of modeling a dual Peacekeeper target launch to determine exhaust emissions of aluminum oxide, hydrogen chloride, and carbon monoxide show that the level of hydrogen chloride would be below the 1-hour Air Force standard, but would exceed the peak hydrogen chloride standard for a short duration. Other emissions were determined to be within NAAQS and Alaska AAQS. A single Peacekeeper target launch would be within NAAQS, Alaska AAQS, and U.S. Air Force standards. Significant air quality impacts due to target launches are not anticipated.</td>
<td>Increase in air emissions from construction and operation of the In-Flight Interceptor Communication System Data Terminal and TPS-X Radar would not affect the region’s current attainment status.</td>
<td>Increase in air emissions from operation would not affect the region’s current attainment status.</td>
</tr>
<tr>
<td><strong>Airspace</strong></td>
<td>The use of the required scheduling and coordination with the Federal Aviation Administration and issuance of Notices to Airmen would reduce potential impacts to airspace status or use to the level of insignificance.</td>
<td>The use of the required scheduling and coordination with the Federal Aviation Administration and issuance of Notices to Airmen would reduce potential impacts to airspace status or use to the level of insignificance.</td>
<td>Construction and operation would not impact airspace.</td>
<td>Operation would not impact airspace.</td>
</tr>
<tr>
<td><strong>Biological Resources</strong></td>
<td>Loss of small amount of mainly upland vegetation. Fence line would likely be altered to avoid impacts to wetlands. Temporary, short-term startle effects from noise to wildlife and birds. Although a remote possibility, individual animals close to the water’s surface could be hit by debris.</td>
<td>Loss of small amount of mainly upland vegetation. Fence line would likely be altered to avoid impacts to wetlands. Temporary, short-term startle effects from noise to wildlife and birds. Although a remote possibility, individual animals close to the water’s surface could be hit by debris.</td>
<td>Loss of small amount of mainly upland vegetation. Temporary, short-term startle effects from noise to terrestrial wildlife and birds. Short-term operational impacts to wildlife (non-listed only) from security lighting and noise from electrical generators required for the site. The TPS-X Radar is not expected to radiate lower than 5 degrees above horizontal and the relatively small radar beam would normally be in motion which reduces the probability of bird species remaining within this limited region of space.</td>
<td>Mobile sensors necessary to support Ground-Based Midcourse Defense Extended Test Range activities would be located on existing disturbed areas with minimal effect to biological resources.</td>
</tr>

<tr>
<td><strong>Health and Safety</strong></td>
<td>An Electromagnetic Radiation/Electromagnetic Interference survey and analysis and DD Form 1494 would be required as part of the spectrum certification and frequency allocation process. Implementation of Sea-Based Test X-Band Radar operational safety procedures, including establishment of controlled areas, and limitations in the areas subject to illumination by the radar units, would preclude any potential safety hazard to either the public or workforce. These limitations would be similar to the existing Ground-Based Radar Prototype on Kwajalein, resulting in no impacts to health and safety.</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Utilities</strong></td>
<td>Electricity demand, potable water consumption, wastewater usage, and solid waste disposal would be handled by existing facilities.</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Visual and Aesthetic Resources</strong></td>
<td>Visual impacts would be minor as the Sea-Based Test X-Band Radar would be comparable to ships passing along the horizon. The Sea-Based Test X-Band Radar would be moored at an adequate distance away from the shore and would not obstruct panoramic views. Visual resources could also be affected by the Sea-Based Test X-Band Radar if it is in the line-of-sight from boats to the island. However, the Sea-Based Test X-Band Radar would only inhibit the view of the island temporarily, as the boat passes by.</td>
<td></td>

<tr>
<td><strong>Air Quality</strong></td>
<td>The Sea-Based Test X-Band Radar would not be considered a stationary source and would not require a Prevention of Significant Deterioration review or a Title V permit. Air emissions from the operation of the Sea-Based Test X-Band Radar would be in compliance with appropriate State Implementation Plans.</td>
</tr>
<tr>
<td><strong>Airspace</strong></td>
<td>Potential impacts to airspace would be minimized by adhering to operational requirements. An Electromagnetic Radiation/Electromagnetic Interference survey and analysis and DD Form 1494 would be required as part of the spectrum certification and frequency allocation process. The Sea-Based Test X-Band Radar high energy radiation area would be configured to minimize potential impacts to aircraft and other potentially affected systems, and would be published on aeronautical charts. In addition, Sea-Based Test X-Band Radar information would be published in the Airport Facility section of the FAA Airport Guide, and local Notices to Airmen would be issued. Flight service personnel would brief pilots flying in the vicinity about the Sea-Based Test X-Band Radar high energy radiation area.</td>
</tr>
<tr>
<td><strong>Biological Resources</strong></td>
<td>Minor, short-term impacts from construction noise, such as startling and temporary displacement. The Sea-Based Test X-Band Radar is not expected to radiate lower than 10 degrees above horizontal at the mooring site, and the relatively small radar beam would normally be in motion which reduces the probability of bird species, marine mammals, or sea turtles remaining within this limited region of space. The Sea-Based Test X-Band Radar vessel would incorporate marine pollution control devices such as keeping decks clear of debris, cleaning spills and residues, and engaging in spill and pollution prevention practices in compliance with the Uniform National Discharge Standards provisions of the Clean Water Act. The potential for impacts to marine mammals or sea turtles due to an accidental release of diesel fuel is considered low. The relatively slow speed of the Sea-Based Test X-Band Radar platform would preclude the potential for collision with a free-swimming marine mammal. No significant long-term adverse impacts are anticipated to seabirds and shorebirds, Guadalupe fur seals, California sea lions, northern elephant and harbor seals, and sea otters or to widely distributed, open-water species such as gray and killer whales.</td>
</tr>
<tr>
<td><strong>Hazardous Materials and Hazardous Waste</strong></td>
<td>The small quantities of potentially hazardous materials and waste generated during construction activities would result in generation of additional waste which would be accommodated in accordance with existing policies and regulations. The Sea-Based Test X-Band Radar would follow U.S. Navy requirements that to the maximum extent practicable, ships shall retain hazardous waste aboard ship for shore disposal. In compliance with Uniform National Discharge Standards, the Sea-Based Test X-Band Radar vessel would incorporate marine pollution control devices, such as keeping decks clear of debris, cleaning spills and residues and engaging in spill and pollution prevention practices, in design or routine operation. Handling and disposal of hazardous materials and waste would be in accordance with State of California, Environmental Protection Agency, Occupational Safety and Health Administration, Department of Transportation, and Department of Defense policies and procedures.</td>
</tr>
<tr>
<td><strong>Health and Safety</strong></td>
<td>An Electromagnetic Radiation/Electromagnetic Interference survey and analysis and DD Form 1494 would be required as part of the spectrum certification and frequency allocation process. ### Air Quality
The Sea-Based Test X-Band Radar would not be considered a stationary source and would not require a Prevention of Significant Deterioration review or a Title V permit. Air emissions from the operation of the Sea-Based Test X-Band Radar would be in compliance with appropriate State Implementation Plans. Dust suppression measures such as periodic watering of areas being graded, minimizing unnecessary traffic, reducing vehicle speeds near the work areas, and wet sweeping or otherwise removing soil and mud deposits from paved roadways and parking areas, would be used as required for support facility construction.

### Airspace
Potential impacts to airspace would be minimized by adhering to operational requirements. An Electromagnetic Radiation/Electromagnetic Interference survey and analysis and DD Form 1494 would be required as part of the spectrum certification and frequency allocation process. The Sea-Based Test X-Band Radar high energy radiation area would be configured to minimize potential impacts to aircraft and other potentially affected systems, and would be published on aeronautical charts. In addition, Sea-Based Test X-Band Radar information would be published in the Airport Facility section of the FAA Airport Guide, and local Notices to Airmen would be issued. Flight service personnel would brief pilots flying in the vicinity about the Sea-Based Test X-Band Radar high energy radiation area.

### Biological Resources
Minor, short-term impacts from construction noise, such as startling and temporary displacement. The Sea-Based Test X-Band Radar is not expected to radiate lower than 10 degrees above horizontal at the mooring site, and the relatively small radar beam would normally be in motion which reduces the probability of bird species, marine mammals, or sea turtles remaining within this limited region of space. The Sea-Based Test X-Band Radar vessel would incorporate marine pollution control devices such as keeping decks clear of debris, cleaning spills and residues, and engaging in spill and pollution prevention practices in compliance with the Uniform National Discharge Standards provisions of the Clean Water Act. The potential for impacts to marine mammals or sea turtles due to an accidental release of diesel fuel is considered low. The relatively slow speed of the Sea-Based Test X-Band Radar platform would preclude the potential for collision with a free-swimming marine mammal. No significant long-term adverse impacts are anticipated to seabirds, shorebirds (bald eagle), Chinook salmon, bull trout, or widely distributed, open-water species such as humpback, blue, fin, sei, and sperm whales; green, leatherback, and loggerhead sea turtles; and steller sea lions.

### Hazardous Materials and Hazardous Waste
The small quantities amount of potentially hazardous materials used during construction activities would result in generation of added wastes that would be accommodated in accordance with existing protocol and regulations. The Sea-Based Test X-Band Radar would follow U.S. Navy requirements that, to the maximum extent practicable, ships shall retain hazardous waste aboard ship for shore disposal. In compliance with Uniform National Discharge Standards, the Sea-Based Test X-Band Radar vessel would incorporate marine pollution control devices, such as keeping decks clear of debris, cleaning spills and residues and engaging in spill and pollution prevention practices, in design or routine operation. Handling and disposal of hazardous materials and hazardous waste would be in accordance with State of Washington, Environmental Protection Agency, Occupational Safety and Health Administration, Department of Transportation, and Department of Defense policies and procedures.

### Health and Safety
An Electromagnetic Radiation/Electromagnetic Interference survey and analysis and DD Form 1494 would be required as part of the spectrum certification and frequency allocation process. Implementation of Sea-Based Test X-Band Radar operational safety procedures, including establishment of controlled areas, and limitations in the areas subject to illumination by the radar units, would preclude any potential safety hazard to either the public or workforce. These limitations would be similar to the existing Ground-Based Radar Prototype on Kwajalein, resulting in no impacts to health and safety.

<tbody>
<tr>
<td><strong>Socioeconomics</strong></td>
<td>Construction activities related to the implementation of Alternative 1 would not cause any displacement of populations, residences, or businesses within the city of Everett and surrounding areas. The additional construction personnel and the 50 on-board personnel associated with the proposed action would represent both a potential increase in local service-based employment opportunities and a small, but positive economic impact to the local economy. Visual impacts to the surrounding area would be partially mitigated by the fact that the Sea-Based Test X-Band Radar would be an additional structure on an existing military base immediately surrounded by industrial land uses thereby reducing the potential impacts to property values. Particularly in a port area where the mooring of ships and other Navy activities are a normal incidence of the military presence, a reduction of property values from the visual effect of large vessels in the harbor does not seem likely. Based on safety standards and documented analysis, the proposed operation of the Sea-Based Test X-Band Radar in port, with appropriate controls and coordination, will not pose a hazard to personnel or equipment. It is however worth noting that the perception by many persons that project related use of electromagnetic radiation does indeed pose a health risk could potentially lead to a diminished level of desirability, and therefore demand, for certain properties within the areas perceived to be affected; thereby having the potential to adversely affect property values within those areas. Given that this impact would be solely attributable to individual interpretation of a perceived risk, the extent and nature of the potential fall in property values, if any, and the areas affected are unable to be determined.</td>
<td></td>
</tr>
<tr>
<td><strong>Transportation</strong></td>
<td>Adequate coordination would prevent any conflicts with tribal fishing areas, and would prevent any impacts on current shipping schedules, ship-borne commerce or general transit.</td>
<td></td>
</tr>
<tr>
<td><strong>Utilities</strong></td>
<td>Electricity demand, potable water consumption, wastewater usage, and solid waste disposal would be handled by existing facilities.</td>
<td></td>
</tr>
<tr>
<td><strong>Visual and Aesthetic Resources</strong></td>
<td>While there is a high amount of viewer concern, the Sea-Based Test X-Band Radar would be considered visually compatible with the port and present military uses; therefore, only moderate impacts are expected to visual resources.</td>

Implementation of Sea-Based Test X-Band Radar operational safety procedures, including establishment of controlled areas, and limitations in the areas subjected to illumination by the radar units, would preclude any potential safety hazard to either the public or workforce. These limitations would be similar to the existing Ground-Based Radar Prototype on Kwajalein, resulting in no impacts to health and safety.</td>
</tr>
<tr>
<td><strong>Transportation</strong></td>
<td>Coordination with local Native American groups would be necessary to prevent any impacts to native fishing areas, particularly during the August salmon run and during other peak fishing seasons. Coordination would be required with the U.S. Coast Guard to lessen requirements for channel (Valdez Narrows) closure and preclude potential delays of oil tankers utilizing the area, as well as to establish any required security zone at the mooring site.</td>
</tr>
<tr>
<td><strong>Utilities</strong></td>
<td>Electricity demand, potable water consumption, wastewater usage, and solid waste disposal would be handled by existing facilities.</td>
</tr>
<tr>
<td><strong>Visual and Aesthetic Resources</strong></td>
<td>Because Valdez is the site of the terminus of the Trans-Alaska Pipeline, numerous oil tankers are consistently entering Prince William Sound which would limit the impacts to visual resources caused by the Sea-Based Test X-Band Radar. However, adverse impacts to visual resources could occur due to some concerned viewers and a high scenic integrity rating for the location.</td>
</tr>
<tr>
<td>Resource Category</td>
<td>Ground-Based Interceptor and Target Intercept Debris</td>
</tr>
<tr>
<td>-------------------------</td>
<td>------------------------------------------------------</td>
</tr>
<tr>
<td>Airspace</td>
<td>Where flight paths cross intercept debris areas, air traffic would be rerouted or rescheduled during a 3- to 4-hour period, approximately five times a year. Routing around the debris areas would be handled in a manner similar to severe weather. The additional time for commercial aircraft to avoid the area would generally be less than 10 minutes at cruising altitudes and speeds.</td>
</tr>
<tr>
<td>Biological Resources</td>
<td>No adverse impact.</td>
</tr>
<tr>
<td>Health and Safety</td>
<td>Testing operations pose potential impacts that would be minimized through pre-flight planning and coordination with the Federal Aviation Administration and issuance of Notices to Airmen and Notices to Mariners.</td>
</tr>
<tr>
<td>Transportation</td>
<td>Prior warning of Ground-Based Midcourse Defense Extended Test Range activities would allow commercial shipping to follow alternative routes away from the test area.</td>
</tr>

1.0 PURPOSE OF AND NEED FOR THE PROPOSED ACTION

1.1 INTRODUCTION

The National Environmental Policy Act (NEPA) of 1969 as amended (42 United States Code [USC] 4321, et seq.), the Council on Environmental Quality (CEQ) Regulations for Implementing the Procedural Provisions of NEPA (40 Code of Federal Regulations [CFR] 1500-1508), Department of Defense (DoD) Instruction 4715.9, Environmental Planning and Analysis, and the applicable Service environmental regulations that implement these laws and regulations, direct DoD officials to consider environmental consequences when authorizing and approving federal actions. Accordingly, this Environmental Impact Statement (EIS) examines the potential for impacts to the environment as a result of the proposed construction, operation, and test activities associated with the proposed Ground-Based Midcourse Defense (GMD) Extended Test Range (ETR). Under this Proposed Action, additional test facilities, including the Sea Based Test X-Band Radar (SBX), test equipment, infrastructure, and communications links would be constructed and operated for the purpose of providing more realistic GMD flight testing in the North Pacific Region. Existing range facilities would be enhanced, and additional launch and support sites would be established to support more robust missile flight tests.

1.2 BACKGROUND

Within the DoD, the Missile Defense Agency (MDA) (formerly the Ballistic Missile Defense Organization) is responsible for developing and testing a conceptual Ballistic Missile Defense System (BMDS). There are three segments that make up the BMDS: Boost Phase Defense, Midcourse Defense, and Terminal Defense. Each segment of the BMDS is being developed to destroy an attacking missile in the corresponding boost, midcourse, or terminal phase of its flight (see figure 1.2-1). The boost phase is the portion of a missile’s flight in which it produces thrust to gain altitude and acceleration. This phase usually lasts between 3 to 5 minutes. During the midcourse phase, which occurs outside much of the Earth’s atmosphere for medium- and long-range missiles, the missile coasts in a ballistic trajectory. This phase can last as long as 20 minutes in the case of intercontinental ballistic missiles. During the terminal phase, the missile enters the lower atmosphere and continues on to its target. This phase lasts approximately 30 seconds for intercontinental ballistic missiles. Each segment of the BMDS is composed of one or more elements, each of which consists of an integrated set of technology components, such as interceptors, radars, and communications links, which provide a unique missile defense capability. GMD is one such element.

The MDA’s ultimate goal is to develop an integrated BMDS that would be able to destroy an attacking missile in any phase of its flight. However, each prospective element of the different segments of the conceptual BMDS is at a different stage of development and would have a different timetable for integration into the eventual BMDS. Consequently, each element is being designed to provide some capability to defend against an attacking ballistic missile independent of other elements within an overall system. The BMDS development concept is to integrate
Phases of Ballistic Missile Flight and the Concept for Ground-Based Midcourse Defense

EXPLANATION
Note: Locations in this figure are for illustrative purposes only and are notional.

Figure 1.2-1
promising technologies into BMDS elements as their capabilities are demonstrated through testing.

The GMD Joint Program Office, within the MDA, is responsible for overseeing the development of the GMD element, which is designed to intercept long-range ballistic missiles during the midcourse (ballistic) phase of their flight, before they reenter the Earth’s lower atmosphere. An operational GMD element architecture would include the five key components listed below. An illustration of these components, within the concept for GMD testing and operations, is included in figure 1.2-1.

- Ground-Based Interceptors (GBIs)
- X-Band Radar (XBR)
- GMD Fire Control/Communications (GFC/C) facilities and links
- Upgraded Early Warning Radars
- Space-Based Detection Capability

In July 2000, the MDA completed the National Missile Defense (NMD) Deployment EIS to support decisions concerning deployment of a GMD (formerly NMD) element (Ballistic Missile Defense Organization, 2000). At the direction of the Secretary of Defense, the MDA refocused the GMD element on operationally realistic testing under the concept of the GMD ETR. This EIS serves to analyze the proposed GMD ETR actions and alternatives for potential impacts on the environment.

On 17 December 2002, President George W. Bush announced plans to begin deployment of an initial set of missile defense capabilities by the year 2004. The MDA proposes to use existing test facilities and infrastructure to the extent possible in fielding these initial capabilities. Consequently, some of the assets proposed for this initial capability could share assets in common with some of those analyzed as part of the GMD ETR. Additional facilities or activities required at Vandenberg Air Force Base (AFB) to support an initial missile defense capability that would not involve test assets are outside the scope of this EIS. A separate NEPA analysis is being prepared to analyze the environmental impacts of fielding this initial capability. Where there may be cumulative environmental effects at Vandenberg AFB from the combined test and initial missile defense capability activities, they will be discussed in the cumulative effects section of this EIS, as applicable.

1.3 PURPOSE OF THE PROPOSED ACTION

The proliferation of weapons of mass destruction and long-range ballistic missile technology is increasing the threat to our national security. The GMD element would defend all 50 states against limited ballistic missile attack. The Secretary of Defense has identified the need to gain a higher level of confidence in the capability of the GMD to defend the United States through more robust interceptor flight tests under more realistic conditions.

The purpose of the Proposed Action is to provide for more realistic flight tests in support of development of the GMD element. The ETR would achieve this by providing additional target
and interceptor launch locations, and sensors, in a wider range of intercept engagements and under more stressing conditions.

1.4 NEED FOR THE PROPOSED ACTION

More realistic testing using trajectories and distances that closely resemble those required of an operational element is needed to ensure the GMD element being developed has the capability to defend the United States against limited missile attacks. To meet this need, the MDA proposes to gain a higher level of confidence in GMD’s capabilities to defend the United States through more robust interceptor tests under more realistic conditions.

Currently, the existing test ranges located in the Pacific Region and elsewhere are limited in their capabilities to provide for a geographically dispersed operational environment, suitable for GMD types of testing. As a result, current GMD element testing is constrained by how missile flight tests can be conducted, and in opportunities for multiple engagement scenarios.

1.5 SCOPE OF THE ENVIRONMENTAL IMPACT STATEMENT

The GMD testing would be of two types: (1) validation of the GMD operational concept and (2) more robust GMD element testing. The facilities and operations to validate the GMD operational concept and improve the realism of GMD element testing are each a part of the GMD Test Bed. Each part of the test bed, however, serves a different test function and has independent utility, purpose, and need. The independent parts of the test bed also have different implementation schedules. Consequently, the independent parts of the test bed are being evaluated in separate NEPA analyses. Validation of the operational concept is analyzed in the Ground-Based Midcourse Defense (GMD) Validation of Operational Concept (VOC) Environmental Assessment (EA) (U.S. Army Space and Missile Defense Command, 2002a). These actions are designed to validate potential non-launch activities associated with the GMD operational concept by testing the interoperability of the GMD components in a realistic environment. The EA analyzed construction, testing, and support activities at Fort Greely, Clear Air Force Station, and Eielson AFB in central Alaska; Eareckson Air Station on Shemya, Alaska; and Beale AFB, California.

The second type of GMD testing, which is analyzed in this EIS, would involve more robust interceptor flight tests with participation of other GMD components such as SBX and In-flight Interceptor Communication System Data Terminals (IDTs) to achieve more realistic testing. This enhanced ETR flight testing would be accomplished through the extension of existing Pacific Region test range areas that are currently supporting GMD test activities. By extending these test range areas, the realism of GMD testing would be increased through the use of multiple missile engagement scenarios, trajectories, geometries, distances, and speeds of targets and interceptors that more closely resemble those for which an operational system would provide an effective defense. Most tests would include the launch of a target missile; tracking by range and other land-based, sea-based, airborne, and space-based sensors; launch of a GBI; and missile intercepts at high altitudes over the Pacific Ocean. Some test events proposed for later in the program would require multiple target and interceptor missile flights to validate GMD element performance.
Under the proposed GMD ETR concept, target missiles would be launched from Ronald Reagan Ballistic Missile Defense Test Site (RTS) at U.S. Army Kwajalein Atoll (USAKA) in the Marshall Islands; Kodiak Launch Complex (KLC), Alaska; Vandenberg AFB, California; Pacific Missile Range Facility (PMRF) on Kauai, Hawaii; and/or from mobile platforms situated in the North Pacific Ocean. Figure 1.5-1 shows these and other GMD ETR test and test support locations. Interceptor missiles would be launched from RTS, KLC, and/or Vandenberg AFB. Dual target and interceptor missile launches would occur in some scenarios. Existing, modified, or new launch facilities and infrastructure would support these launch activities at the various locations.

Also in support of these launches, missile acquisition and tracking would be provided by existing sea-based sensors, an SBX, and existing land-based sensors in the Pacific Region; a transportable system radar (TPS-X) positioned at Vandenberg AFB, KLC, RTS, or PMRF; the existing prototype XBR at RTS; and existing/upgraded radars at Beale AFB, Clear Air Force Station, and Eareckson Air Station (figure 1.5-1).

IDTs would be constructed at GBI launch sites or placed on a sea-based platform near the proposed GBI launch sites and expected intercept areas or a combination of both. Commercial satellite communications (COMSATCOM) terminals would also be constructed at launch sites that do not have fiber optic communication links and at other locations in the mid-Pacific Region.

Alternative architectures for achieving more realistic interceptor flight tests in the Pacific Region are organized around potential additional interceptor missile launch sites, with other test components being located to provide maximum test effectiveness. For analysis purposes in this EIS, three alternative GMD Test Bed architectures have been identified based on developing additional missile launch capability for GMD testing at:

1. KLC and RTS; or
2. Vandenberg AFB and RTS; or
3. KLC, Vandenberg AFB, and RTS.

A total of approximately 10 launches per year is anticipated for the entire GMD ETR test program. For each of the alternatives, the proposed GMD ETR activities could include up to five missile launches (interceptors and/or targets) from a specific launch facility per year. The GMD ETR activities would be expected to occur over a period of approximately 10 years following a decision to proceed.

In accordance with CEQ Regulations (40 CFR 1502.14(d)), this EIS also analyzes the No Action Alternative, which serves as the baseline from which to compare the alternatives to the Proposed Action. Under the MDA No Action Alternative, the GMD ETR would not be established, and interceptor and target launch scenarios would not be fully tested under operationally realistic conditions. All existing facilities and launch areas, however, would continue current operations, including support of ongoing GMD-related activities. Existing launch sites and test resources would continue to be used in GMD test scenarios whenever practical.
Although Midway was an alternative site in the Draft EIS, MDA has determined that it is no longer a reasonable alternative and will not be a proposed site for ETR activities. The IDT on-board the SBX would perform the function that had been planned for Midway. The discussion of Midway has been retained in the Final EIS, however, in order to preserve the work that has already been performed.

**EXPLANATION**

Note: Although Midway was an alternative site in the Draft EIS, MDA has determined that it is no longer a reasonable alternative and will not be a proposed site for ETR activities. The IDT on-board the SBX would perform the function that had been planned for Midway. The discussion of Midway has been retained in the Final EIS, however, in order to preserve the work that has already been performed.

---

**Potential GMD ETR Test and Test Support Locations**

**Pacific Ocean**

---

**Figure 1.5-1**
The Federal Aviation Administration (FAA) will also rely on this EIS to support a site operator license renewal at KLC. The FAA No Action Alternative would be to not issue a license renewal for KLC.

### 1.6 DECISIONS TO BE MADE

The initial decision to be made by the MDA is whether to implement the Proposed Action to construct and operate additional GMD test facilities, test equipment, infrastructure, and communication links to enable the MDA to conduct enhanced GMD element testing; or to choose the MDA’s No Action Alternative. If the MDA selects the Proposed Action, then a second decision would be made as to which of the three alternative missile launch scenarios and locations would most effectively meet the objectives of the enhanced test program. At the completion of the EIS analysis process, these decisions will be documented in a Record of Decision (ROD), to be published in the *Federal Register*.

The FAA, which is a cooperating agency for this EIS, will also rely on this analysis to support its environmental determination for a launch site operator license renewal at KLC. The FAA’s alternatives to be evaluated include renewing the current launch site operator license with no modification as identified in the MDA’s No Action Alternative; issuing a license for the list of activities as identified in the MDA’s Alternative 1; issuing a license for the list of activities as identified in the MDA’s Alternative 2; and FAA’s No Action Alternative, which would be to not issue a license renewal for the KLC. For the purposes of the FAA’s analysis of proposed activities at KLC, the MDA’s Alternative 1 is the same as the MDA’s Alternative 3.

At the conclusion of this environmental review process the FAA will issue a separate ROD to support its licensing determination at KLC. The FAA will draw its own conclusions from the analysis presented in this EIS and relevant information contained in the FAA’s earlier site license *Environmental Assessment of the Kodiak Launch Complex, Kodiak Island, Alaska* (Federal Aviation Administration, 1996) and assume responsibility for its ROD and any related mitigation measures. Further discussion on this particular issue is provided in section 1.7.

### 1.7 COOPERATING AGENCIES

In accordance with CEQ Regulations (40 CFR 1501.6), an invitation for cooperating agency status was extended to the FAA for consultation, review, and comment on the EIS. A cooperating agency is an agency with either jurisdiction over a proposed federal action or special expertise about the environmental effects caused by the action.

The FAA, Office of the Associate Administrator for Commercial Space Transportation, is a cooperating agency because of its regulatory authority in licensing the operation of KLC, as defined in 49 USC Subtitle IX—Commercial Space Launch Activities, 49 USC 70101-70121, and supporting regulations. The FAA has special expertise and legal responsibility related to the licensing of commercial launch facilities. The FAA is responsible for providing oversight and coordination for licensed launches and protecting the public health and safety, safety of property, and national security and foreign policy interests of the United States. Licensing of launches and reentries, operating a launch or reentry site, or some combination, is considered a federal action.
for which environmental impacts must be considered as part of the decision making process as required by NEPA.

Alaska Aerospace Development Corporation (AADC) applied for and was granted a launch site operator license for the operation of KLC in September 1998. A license to operate a launch site remains in effect for 5 years from the date of issuance unless surrendered, suspended, or revoked before the expiration of the term and is renewable upon application by the licensee (14 CFR 420.43, Duration). The existing FAA license for the operation of KLC will expire in September 2003.

Should the FAA not reissue a launch site operator’s license for KLC to conduct launches, the MDA would be required to choose an alternative that does not include KLC. KLC is the only launch complex evaluated in the EIS that requires a license from the FAA.

An environmental review is just one component of the FAA’s licensing process. FAA Order 1050.1D, Policies and Procedures for Considering Environmental Impacts, describes the Agency’s procedures for implementing NEPA. Specifically, it requires that the FAA decision making process facilitate public involvement by including consideration of the effects of the Proposed Action and alternatives; avoidance or minimization of adverse effects attributable to the Proposed Action; and restoration and enhancement of resources, and environmental quality of the nation. These requirements will be considered in the FAA’s licensing decision.

In addition to the environmental review and determination, applicants must complete a policy review and approval, safety review and approval, payload review and determination, and a financial responsibility determination. The purpose of the Policy Review and Approval process is to determine whether or not the information in the license application presents any issues affecting U.S. national security or foreign policy interests, or international obligations of the United States. The purpose of the Safety Review and Approval process is to determine whether an applicant can safely conduct the launch of the proposed launch vehicle(s) and any payload. The purpose of the Payload Review and Determination is to determine whether a license applicant or payload owner or operator has obtained all required licenses, authorization, and permits. The purpose of the Financial Responsibility Determination is to ensure that all commercial licensees demonstrate financial responsibility to compensate for the maximum probable loss from claims by a third party for death, bodily injury, or property damage or loss resulting from an activity carried out under the license; and the U.S. Government against a person for damage or loss to government property resulting from an activity carried out under the license. All of these reviews, including the environmental review, must be completed prior to issuing a license. All FAA safety analyses would be conducted separately and would be included in the terms and conditions of the license.

A license to operate a launch site authorizes a licensee to offer its launch site to a launch operator for each launch point for the type and weight class of launch vehicle identified in the license application and upon which the licensing determination is based. Issuance of a license to operate a launch site does not relieve a licensee of its obligation to comply with any other laws or regulations, nor does it confer any proprietary, property, or exclusive right in the use of airspace or outer space (14 CFR 420.41).
1.8 SUMMARY OF THE PUBLIC SCOPING PROCESS

The CEQ Regulations implementing NEPA require an open process for determining the scope of issues related to the Proposed Action and its alternatives. Comments and questions received, as a result of this process, assist the DoD in identifying potential concerns and environmental impacts to the human and natural environment.

The GMD ETR EIS public scoping period began on 28 March 2002, when the Notice of Intent to prepare an EIS was published in the *Federal Register*. The scoping comment period was originally scheduled to end on 10 May 2002, but was extended to 20 May 2002 in response to public request. Subsequently, inclusion of the SBX in the EIS analysis extended scoping and the comment period even further, through 20 December 2002.

A number of methods were used to inform the public about the GMD ETR Program and of the locations of the scheduled scoping meetings. These included:

- The Notice of Intent announcement in the *Federal Register*
- Paid advertisements in local and regional newspapers

Public scoping meetings were held at the locations listed in table 1.8-1. During these public scoping meetings, attendees were invited to ask questions and make comments to the program representatives at each meeting. In addition, written comments were received from the public and regulatory agencies at the scoping meeting, and by letter and e-mail during the extended comment period. Comments received from the public and agencies pertaining to specific resource areas and locations were considered, and more detailed analysis was provided in the EIS. Those comments received from the public concerning DoD policy and program issues are outside the scope of what is required to be analyzed in an EIS.

Native Village Meetings

A series of village coordination meetings was held on Kodiak Island in June and July 2002 in partial fulfillment of a pledge from the GMD Joint Program Office to reach out to Native residents to explain the Proposed Action at KLC. The team visited the villages of Akhiok, Ouzinkie, Port Lions, Afognak, Kodiak, and Larsen Bay.

Several generic issues were raised, including the following:

- The environmental consequences of flying rockets from KLC
- The inquiry from the Village of Old Harbor about the need for a fallout shelter
- Job opportunities associated with the Proposed Action
- Most village attendees expressed feelings of patriotism and support for what was being planned

Agency Meetings

An agency meeting was held in the offices of the Alaska Division of Governmental Coordination in Anchorage in April 2002 to provide an overview of the Proposed Action to the represented agencies and to solicit input on the EIS. Agencies represented at this meeting included the U.S. Fish and Wildlife Service (USFWS), the Alaska Department of Fish and Game, the U.S. Army Corps of Engineers, the U.S. Coast Guard, and the Alaska Department of Natural Resources. Some of the comments from the agencies are listed below:

- The USFWS recommended that an alternative site to the current proposed launch site at KLC should also be considered, if possible, because this ridge area is a sensitive area and there are public use concerns.
- The agencies requested more detailed information regarding the Proposed Action and alternatives.
- A trip with the agencies to the proposed construction site at Kodiak was suggested and agreed upon for the near future.
- A trip to Kodiak was conducted in May of 2002. The USFWS was the only agency in attendance. After reviewing the proposed KLC sites, the concern over the ridge area noted during the meeting was lessened and the visit focused on visual impacts.

An additional agency meeting was held in the offices of the Alaska Division of Governmental Coordination Offices in Anchorage in November 2002 to provide additional information regarding the potential siting of the SBX at Adak or the Port of Valdez, and to solicit input on the Coordinating Draft EIS. Agencies represented included the Alaska Department of Environmental Conservation, the U.S. Army Corps of Engineers, and the Alaska Department of Natural Resources. Some of the comments from the agencies are listed below:

- Migratory bird site adjacent to Valdez is an Aquatic Resource of National Importance. Air quality is a potential concern.
- Valdez Narrows is closed when a tanker is passing through.
An Alaska Department of Natural Resources permit would be required for all actions within 4.8 kilometers (3 miles) of the shore. This would include barge landing sites and mooring sites. Mooring sites would also require a Section 10 Permit.

Need to add Standard Operating Procedures (SOPs) for debris recovery in case of an accident at KLC, since this operation would have the highest probability for perchlorate contamination.

An agency meeting was held in Honolulu in September 2002 with representatives from the USFWS and the FAA. This meeting centered primarily on the potential siting of the SBX at Pearl Harbor. Some of the comments from the agencies included:

- Questions from the FAA on the proposed operation of the radar and the effects of radiological hazards and interference with air traffic at the Honolulu International Airport
- Questions from the USFWS mainly concerning the effects of the radar on bird populations

An agency meeting was also held at Naval Station Everett in October 2002 with representatives from the State of Washington and the U.S. Navy. Some of the comments included:

- Questions on the proposed operation of the radar, potential radiological hazards, and interference with ship traffic
- Questions on the potential introduction of foreign species into open water
- Questions on the effects of the SBX on seabirds, shorebirds, federally threatened fish species, and widely distributed open water species such as whales and turtles

Results of Public Scoping Meetings

The public scoping meetings used an information/exhibit format with a formal presentation on the GMD Program Overview and the Environmental Analysis Process. A sampling of some of the comments expressed by the public included:

- Concern about the chemicals in the air and the harm that they will do to the environment
- Concern about the pristine fisheries and wilderness, and belief that a thorough investigation of the effects of launch activities should occur in the EIS
- Concern that the EIS could never fully address all the short- and long-term impacts around KLC
- Concern about the expansion of KLC, since the facility is located in a seismically active area
- Concern about putting valuable resources of Kodiak Island at risk due to toxic substances integral to missile launch operations
- Concern with the hazardous materials that are released in the explosion of a rocket, in flight, on the pad, or in a launch silo; the EIS should address the effects of all potential rocket fuels and payloads
- Concern about the safety of the Proposed Action
- Concern about the health hazards from radars such as the X-band
- Concern that mobile telemetry radars will not be limited to the roads and will be taken into sensitive areas and damage will occur to the land
- Concern that GMD is expensive and will require cuts in funding for human services
- Opposition to the U.S. Government’s plan for continuing research and development of the Missile Defense Program
- A desire that additional work be done on measuring the cumulative impacts to the environment
- Concern that the Narrow Cape road on Kodiak Island will be closed

Table 1.8-2 summarizes the number of comments received from the public at the scoping meetings, and from other sources, for each resource category.

1.9 SUMMARY OF DRAFT ENVIRONMENTAL IMPACT STATEMENT
PUBLIC REVIEW PROCESS

The public review and comment period began with the publication of a Notice of Availability (NOA) for the GMD ETR Draft EIS, published in the Federal Register on Friday, 7 February 2003, by the Missile Defense Agency and the Federal Aviation Administration. This initiated a review period for the public and interested agencies to review the Draft EIS and submit their comments. Copies of the Draft EIS were made available for review in local libraries in the areas affected and were provided to those who requested a copy of the EIS. Copies of the Draft EIS were available on the MDA website and were placed in the following public libraries:

- Oxnard Public Library, 251 S. A St., Oxnard, CA 93030
- Kodiak City Library, 319 Lower Mill Bay Rd., Kodiak, AK 99615
- Lompoc Public Library, 501 E North Ave., Lompoc, CA 93436
- Anchorage Municipal Library, 3600 Denali St., Anchorage, AK 99503
- Mountain View Branch Library, 150 S. Bragaw St., Anchorage, AK 99508
- Valdez City Library, 212 Fairbanks, Valdez, AK 99686
- Everett Library, 2702 Hoyt Ave., Everett, WA 98201
- Hawaii State Library, Hawaii Documents Center, 478 South King St., Honolulu, HI 96813
- University of Hawaii at Manoa, Hamilton Library, 2550 The Mall, Honolulu, HI 96822

In conjunction with the Draft EIS review process, seven public hearings were held from 24 February 2003 to 6 March 2003. Detailed information on locations and times for each of the public hearings was published in local and regional newspapers (table 1.9-1) 2 weeks in advance, and public-service announcements and press releases were provided to radio and television stations.

The purpose of the public hearings was to solicit public comments on the environmental areas analyzed and considered in the Draft EIS and to identify environmental issues that the public and Government agencies consider to need further analysis. Chapter 8.0 of this EIS contains a reproduction of the transcripts of the public hearings and responses to comments. Table 1.9-2 lists the location, date, times and number of attendees at the public hearings.

In addition to the public hearings, the public could make comments through a 1-800 telephone number, by sending an email, or by sending a written comment. Chapter 8.0 of this EIS contains a reproduction of the telephone, email, and written comments and responses to those comments. Issues identified by the public were provided to resource specialists working on the Final EIS to ensure that all comments were considered during the preparation of the final document. Table 1.9-3 presents a summary of the number of issues identified for each resource area by location.

1.10 RELATED ENVIRONMENTAL DOCUMENTATION

A number of other EAs and EISs have previously been prepared to support the development of the specific technologies that may be used as part of the GMD element. The information and analyses contained in these NEPA documents were used in the development of this EIS. Several of the documents have been incorporated by reference and are cited in the EIS where applicable. Appendix A includes a brief overview of each of these NEPA documents as well as a link to a website where the documents can be viewed.

Additional environmental documentation would be completed following completion of the GMD ETR EIS. A separate NEPA analysis is being prepared to analyze the environmental impacts of fielding an initial missile defense capability at Vandenberg AFB. Appendix E includes information on permits, licenses, and entitlements that would be required before the proposed actions could proceed.
2.0 DESCRIPTION OF PROPOSED ACTION AND ALTERNATIVES

2.1 GMD Extended Test Range Components and Operations
   2.1.1 Ground-Based Interceptor Systems
   2.1.2 Target Missile Systems
   2.1.3 In-Flight Interceptor Communication System Data Terminal Options
   2.1.4 Sea-Based Test X-Band Radar
   2.1.5 Test Range Sensors and Support Instrumentation
   2.1.6 Flight Test Planning and Operations
   2.1.7 Flight Test Safety
   2.1.8 Flight Test Example Scenarios

2.2 No Action Alternative
   2.2.1 Launch Sites and Other Support Facilities
   2.2.2 Mobile GMD System Elements

2.3 Proposed Action
   2.3.1 Alternative 1
   2.3.2 Alternative 2
   2.3.3 Alternative 3—Combination of Alternatives 1 and 2

2.4 Alternatives Considered But Not Carried Forward
   2.4.1 GBI Launch Location Alternatives
   2.4.2 Target Launch Location Alternatives
   2.4.3 IDT Location Alternatives
   2.4.4 Sea-Based Test X-Band Radar Primary Support Base Alternatives
   2.4.5 Mobile Telemetry and Mobile C-Band Radar Location Alternatives
2.0 DESCRIPTION OF PROPOSED ACTION AND ALTERNATIVES

The Proposed Action is to construct and operate additional launch and test facilities in the Pacific Region, and to conduct more realistic GMD element tests in support of GMD development. The extension of existing U.S. test ranges would increase the realism of GMD testing by using multiple engagement scenarios, trajectories, geometries, distances, and speeds of targets and interceptors that more closely resemble those for which an operational system would provide an effective defense. The GMD ETR testing would include pre-launch activities, launch of targets and GBIs from a number of widely separated locations, and missile intercepts over the Pacific Ocean.

For the purpose of this EIS, a flight test or test event represents a target missile flight, an interceptor missile flight, an intercept of a target missile, or a test of some sensor(s) independent of a missile flight test. Most tests would include the launch of a target missile; tracking by range and other land-based, sea-based, airborne, and space-based sensors; launch of an interceptor missile; target intercept; and debris impacting into broad open areas of the Pacific Ocean. Some test events proposed for later in the program would require multiple target and/or interceptor missile flights to validate GMD system performance. A total of approximately 10 launches per year is anticipated for the entire GMD ETR test program. For each of the alternatives, the proposed GMD ETR activities could include up to five missile launches (interceptors and/or targets) from a specific launch facility per year. The GMD ETR testing activities would likely occur over a period of approximately 10 years following a decision to proceed.

The alternatives for implementing the Proposed Action represent architectures for achieving more realistic interceptor flight tests in the Pacific Region. These architectures are organized around potential additional GBI missile launch sites, with other new and existing test components being located to provide maximum test effectiveness. For analysis purposes in this EIS, three alternative test architectures have been identified based on developing additional launch capability at (1) KLC and RTS, (2) Vandenberg AFB and RTS, and (3) KLC, Vandenberg AFB, and RTS. Each alternative test architecture would include common GMD test components consisting of GBIs, target missiles, IDTs, the SBX, and other sensors and instrumentation.

In addition to the alternatives for the Proposed Action, this EIS also considers the No Action Alternative. Under the No Action Alternative, the GMD ETR would not be established, and additional facilities and components to be used in ETR operations would not be built. Existing launch sites and test range activities, however, would continue at the various locations, including support of ongoing GMD test activities.

Table 2.0-1 lists the test activities and components associated with the alternatives for implementing the Proposed Action. Those actions and components that would be conducted under the No Action Alternative are also included. In the discussions following table 2.0-1, section 2.1 describes the GMD ETR components (i.e., GBIs, target missiles, the SBX, IDTs, and other sensors and instrumentation) and pre-flight/flight test operations that would normally

² Mobile–Air or Sea Launch
³ Midway – Although Midway was an alternative site in the Draft EIS, MDA has determined that it is no longer a reasonable alternative and will not be a proposed site for ETR activities. The IDT on-board the SBX would perform the function that had been planned for Midway. The discussion of Midway has been retained in the Final EIS, however, in order to preserve the work that has already been performed.
⁴ Military Satellite Communications at Eareckson Air Station
occur. Section 2.2 identifies the major activities, components, and locations involved in conducting the No Action Alternative. Section 2.3 describes the locations for implementing each of the Proposed Action alternatives. Lastly, section 2.4 describes those alternatives considered, but not carried forward in this analysis.

2.1 GMD EXTENDED TEST RANGE COMPONENTS AND OPERATIONS

The sections that follow provide a detailed description of the GMD ETR components to be used in program testing. Where applicable, facility and component construction and developmental requirements are described. A discussion on GMD pre-flight and flight test operational requirements is also included.

2.1.1 GROUND-BASED INTERCEPTOR SYSTEMS

The GBI is the “weapon” of the GMD element that would be used in GMD ETR testing. Its mission is to intercept incoming ballistic missile warheads outside the Earth’s atmosphere and destroy them by force of impact. The GBI missile consists of a three-stage solid propellant booster and an Exoatmospheric Kill Vehicle (EKV) (figure 2.1.1-1). The GBI is approximately 16 meters (54 feet) long and 1.3 meters (4.2 feet) in diameter, and it weighs approximately 20.4 to 22.7 metric tons (22.5 to 25 tons).

For the purposes of analysis, each interceptor booster is assumed to contain approximately 20,500 kilograms (45,000 pounds) of solid propellant, and each EKV is assumed to contain approximately 7.5 liters (2 gallons) of liquid fuel and 5.5 liters (1.5 gallons) of liquid oxidizer. These liquid propellants would consist of a form of monomethyl hydrazine and nitrogen tetroxide, respectively. The liquid fuel and liquid oxidizer tanks would arrive at the site fully fueled. For this analysis, it is assumed that the interceptor (booster stages and EKV) would be assembled at the test sites.

The components associated with a typical GBI launch site include the Launch Control Center, range sensors, and IDT. Commercial power would be used during missile flight tests, with a generator serving as backup.

2.1.1.1 Ground-Based Interceptor Transportation, Handling, and Facilities

Interceptor missile boosters, payloads, and support equipment would be transported by air, ship, or over-the-road common carrier truck from U.S. Government storage depots or contractor facilities to the test range. All shipping would be conducted in accordance with Department of Transportation (DOT) regulations. The interceptor would be placed in existing or proposed new facilities for assembly and launch preparation. Applicable safety regulations would be followed in the transport, receipt, storage, and handling of hazardous materials. A small quantity of liquid propellants (approximately 7.5 liters [2 gallons] of liquid fuel and 5.5 liters [1.5 gallons] of liquid
oxidizer) would be used by the EKV. Presently, there are no plans to store liquid propellants onsite other than the preloaded fuel and oxidizer tanks that would be installed on the EKV. The interceptor may arrive at the test range with the EKV attached, or the booster may be shipped separately from the EKV. In either case, the fuel and oxidizer tanks would be installed in the EKV and the helium tanks on the EKV would be pressurized at the test site. If the booster is shipped separately from the EKV, integration and assembly operations would be performed onsite.

An appropriate explosive safety quantity–distance (ESQD) would be established around facilities where interceptors and ordnance are stored or handled as approved by the DoD Explosives Safety Board.

Maximum use would be made of existing infrastructure and facilities at launch sites. Existing facilities would be modified as necessary to support interceptor missile system operations. Additional infrastructure requirements may include onsite road improvements, fencing, electrical service, potable water, and telephone and data transmission lines.

At some locations, new GBI silos or a launch pad would be required. The silos would be approximately 3 meters (10 feet) in diameter and 21 meters (70 feet) long (deep). The pad, if required, would be approximately 53.3 by 53.3 meters (175 by 175 feet).

2.1.1.2 Ground-Based Interceptor Launch Support Operations

Portable equipment used to support interceptor missile testing may include telemetry vans, personnel trailers, and power generators. For the GBI launch site, a typical launch cycle ramp-up would include 55 to 65 people during the first month, 100 to 130 people during the second month, and 205 to 260 people during the third month. Dual launch would include approximately 55 to 65 people during the first month, 120 to 150 people during the second month, and 235 to 300 people during the third month. After a launch, approximately 75 personnel would depart immediately. Personnel would include contractors, military, and U.S. Government civilians.

The GBI operations at the test site may include missile assembly and checkout, installation of the EKV bi-propellant tanks onto the EKV, inspection of the tanks after installation, final inspections, testing and checkout of the loaded EKV assembly, integration of the EKV with the booster, and placement of the interceptors into the silo(s). The EKV may be integrated with the booster in the silo, or it may be integrated with the third booster stage before integration with the remainder of the boosters.

The GMD testing would use dedicated utilities for environmental control of the silos, and activities associated with testing. An offsite commercial supplier would supply primary power to the site, but a backup battery system and onsite backup diesel generators would supply emergency power. Generators for various GBI-related facilities would range in output from approximately 75 to 900 kilowatts (kW). Each generator would also have its own dedicated aboveground fuel storage tank. These dedicated tanks would range in capacity from approximately 15,140 to 75,710 liters (4,000 to 20,000 gallons).
2.1.1.3 Ground-Based Interceptor Security

When interceptor testing occurs, it would be on a campaign basis, and the security for these tests would be on a similar basis. It is estimated that security related activities would occur for approximately 5 weeks for each campaign.

Security requirements would vary for each potential launch location. A program of continuous protection activities would take place during each campaign, such as monitoring the Intrusion Detection System, operating the base station for the security radio system, guard training, providing daily instructions for guards, and making security badges for those who come to the site.

The existing Intrusion Detection System may be expanded as necessary to include all critical buildings associated with GMD operations. This expansion may include the installation of additional intrusion sensors, lighting, closed circuit television, and a monitor for the sensors.

Additional physical protection features may be constructed or placed to protect GMD assets. These may include, but are not limited to, fences, security lighting, bollards, tapered concrete barriers or similar devices, ditching and/or earth mounds, patrol roads, and observation tower(s).

Security vehicles may be on patrol day and night. Each vehicle would have radio equipment that would be in operation while on patrol. Normal patrols would be confined to existing roads. There may be occasions when these vehicles can be expected to go off road.

Public access would be limited in the vicinity of GBI missile storage, handling, and launch facilities.

2.1.2 TARGET MISSILE SYSTEMS

The purpose of target missiles in GMD testing is to provide realistic targets for testing new and evolving GMD interceptor missile and sensor systems. Targets would be used to validate the capabilities of GMD interceptor systems. Targets typically simulate the expected threat, both in physical size and performance characteristics. Target missiles may be launched from fixed land locations, sea launch vessels, or aircraft.

2.1.2.1 Target Missiles

A typical GMD target missile consists of a launch vehicle (booster) and a payload that may include a target reentry vehicle, guidance and control electronics, decoys, and other countermeasures. The target missile would deliver the target reentry vehicle in a variety of configurations. A booster may consist of one or more stages. A stage refers to the number of rocket motors which sequentially activate. Multiple stages allow the missile to fly at higher velocities and altitudes, and for longer distances. Specific target missiles that may be used in ETR flight testing are described in the following sections and in table 2.1.2-1. These target missiles are meant to represent a class or range of targets. Figure 2.1.2-1 shows a comparison of the representative launch vehicles and target missiles and identifies the existing and proposed launch sites.

⁴ U.S. Department of the Navy, 2002b

The target reentry vehicle is the portion of the target missile that is designed to represent threat warheads, or reentry vehicles. The target reentry vehicle would separate from the booster before intercept. Target reentry vehicles typically consist of a steel housing assembly, thermal sensors, guidance and control electronics, radio transmitters and receivers, a power supply (which may include lithium or nickel-cadmium batteries), and a payload section.

**Strategic Target System**

The primary components of the Strategic Target System vehicle (figure 2.1.2-1) are the first and second stage Polaris A3 boosters, the third stage Orbus-1 booster, and the development payloads. The Strategic Target System vehicle can maneuver once away from the launch pad and over the Pacific Ocean.

**Target Launch Vehicle (Minuteman II Derivative)**

The Target Launch Vehicle (TLV) (Minuteman II derivative) (figure 2.1.2-1) consists of three solid-propellant rocket engines and a front system. The TLV target would be designed to accommodate a variety of payload sizes, shapes, and interfaces. The TLV target may include a temporary shroud that protects the front section during the early phases of flight.

**Peacekeeper Target Missile**

The Peacekeeper target missile (figure 2.1.2-1) consists of a modified Peacekeeper missile with three solid propellant rocket motors, a liquid propellant fourth stage, and a reentry system. The reentry system is capable of deploying up to 10 reentry vehicles. Each deployed reentry vehicle follows a ballistic path to its target.

**Trident Target Missile**

The Trident target (figure 2.1.2-1) consists of an extensively modified Trident three-stage, solid propellant, inertial guided U.S. Navy Fleet Ballistic Missile.

- **○** Additional NEPA Documentation Required (ETR EIS)

**NOTE:** Existing GBI launches from Vandenberg Air Force Base are booster verification only, no intercept.

---

**Figure 2.1.2-1**
2.1.2.2 Target Missile Transportation, Handling, Facilities, and Launches

Missile components would be built in contractor facilities and delivered to the launch site by air, barge, and/or over-the-road truck for system assembly and checkout. Missiles would not be shipped with initiators or other explosive devices. Missiles would be tested at the DoD depot activity or contractor’s facility before shipment. All missile components would be packaged in appropriately designed containers, labeled, and handled in accordance with applicable DOT regulations for the transport of hazardous materials. Some missile components may be shipped to an airfield near the launch site and transferred to the launch site by local truck. Trained personnel using only appropriately certified equipment would handle missile components in accordance with approved standard operating procedures.

Ground Launched Target

Ground launched target missiles would include those listed in table 2.1.2-1. Target missile components and support equipment would be transported by air, barge, and/or over-the-road common carrier trucks from U.S. Government storage depots or contractor facilities to an onsite Missile Assembly Building, where the missile components would be assembled for launch. Applicable safety regulations would be followed in the transport and handling of hazardous materials. An appropriate ESQD would be established and maintained around facilities where ordnance is stored or handled. Target missile launch preparation at ground launch sites may include the following activities:

- Construction and/or modification of facilities and infrastructure to support launch preparation and flight test activities
- Transportation, handling, and storage of target missile system components and assemblies
- Assembly and maintenance of target missile and support equipment
- Checkout and testing of target missile system components and assemblies

Maximum use would be made of existing facilities and infrastructure at ground-based launch sites. Existing facilities would be modified and new facilities constructed only as necessary to support target missile system operations.

Land launches of target missiles would be accomplished from a fixed launch pad or silo. Missiles would be assembled and checked out onsite in a Missile Assembly Building, and erected on a launch stool on the pad or transferred to a launch silo before a scheduled launch. Each facility in which a missile is stored or processed would have an ESQD zone established around it. Before launch, a Launch Hazard Area would be established. The Launch Hazard Area is the area that could be affected by pieces of missile debris should an explosion occur on or just above the launch pad or in the event that the missile’s flight must be terminated on the pad or shortly after liftoff. This Launch Hazard Area is cleared of all but mission-essential test personnel during launch operations to ensure personnel are not exposed to missile launch hazards.

The target launch site would be occupied for approximately 2.5 months before a scheduled launch and 2 weeks after a launch. A typical 3-month launch cycle ramp-up would include 25 people during the first month, 55 to 75 people during the second month, and 110 to 150 people during the third month. Dual launch would include 25 people during the first month, 75 to 90...
people during the second month, and 150 to 175 people during the third month. After a launch, approximately 50 personnel would immediately depart, and the remaining personnel would depart after launch site refurbishment. Personnel would include contractors, military, and U.S. Government civilians.

The target missile operations at the test site may include missile assembly and checkout, final inspections, testing and checkout of the reentry vehicle, and placement of the target on the launch pad.

The GMD testing would use dedicated utilities for environmental control of the facilities and activities associated with testing. An offsite commercial supplier would supply primary power to the site, but a backup battery system and onsite backup diesel generators would supply emergency power. Generators for various target missile-related facilities would range in output from approximately 75 to 900 kW. Each generator would also have its own dedicated aboveground fuel storage tank. These dedicated tanks would range in capacity from approximately 15,140 to 75,710 liters (4,000 to 20,000 gallons).

Air Launch Target
A typical Air Launch Target missile would include two refurbished Minuteman II motors, a guidance and control unit, and a simulated reentry vehicle. The rocket motors for Air Launch Targets would be shipped to the air launch aircraft location from U.S. Government or contractor facilities by truck and/or air. Other components, such as the target/pallet assembly, would be shipped to the air launch aircraft location from other contractor locations (as applicable). When the missile boosters and other components arrive at the air launch aircraft location, the motor would be transferred to a Missile Assembly Building or a Booster Assembly Building for installation of the Flight Termination System and integration of the other components. The target reentry vehicle would be attached to the booster; then the booster, pallet and sled assembly, and support equipment would be loaded onto the aircraft.

Applicable safety regulations would be followed in the transport and handling of hazardous materials. An appropriate ESQD would be established and maintained around facilities where ordnance is stored or handled.

Approximately 25 to 30 people would be involved in the transportation, handling, and checkout of the missile. The missile components would arrive approximately 3 weeks before scheduled launch. A roller dock assembly with an 11,340-kilogram (25,000-pound) capacity loader would be required to load the target on its pallet. Other handling and transfer equipment would include a crane, forklifts, and a flatbed trailer equipped with transfer rails for the motor.

Selected installations would be able to accommodate the air launch aircraft and support equipment by using existing support facilities and infrastructure. In addition, aircraft flights from these installations would be a routine activity. Therefore, no construction or additional major equipment would be required.
Air Launch Targets would be launched from specifically configured U.S. Air Force cargo aircraft. This launch would involve a target missile on a standard cargo pallet and specialized pallet. Various target missile configurations could be used depending on the range needed for the particular test. The integrated target/pallet assembly would be loaded into the aircraft and flown to a predetermined drop point. The target/pallet assembly would be pulled from the aircraft by parachute and dropped to a level between approximately 6,096 and 7,620 meters (20,000 and 25,000 feet) above mean sea level. The target would separate from the pallet and then descend via parachutes to approximately 4,100 meters (13,450 feet) above mean sea level. At this altitude, the parachutes would release the target, and motor ignition would occur during free-fall. After firing, the boosters would drop into predetermined areas in the Pacific Ocean. The target would then follow its flight path to interception or to splash down within a designated ocean impact area. The target would be fitted with a Flight Termination System to terminate the flight if unsafe conditions develop. Figure 2.1.2-2 depicts a typical aerial target extraction from the aircraft and the launch sequence.

![Diagram of typical aerial target extraction and launch](image-url)
Sea Launch Target

Sea launches of target missiles would be conducted using specially configured missiles and a Mobile Launch Platform (MLP) based at a port with approved explosive handling capabilities. The Sea Launch Target missile would be obtained by modifying an existing Strategic Target System or Minuteman II target missile.

Target missiles and support equipment would be transported from U.S. Government storage depots or contractor facilities in accordance with DOT regulations. They would be placed in secure storage until assembly and launch preparation. Applicable safety regulations would be followed in the transport and handling of hazardous materials. An appropriate ESQD would be established and maintained around facilities where ordnance is stored or handled.

Approximately 50 people would be involved in the transportation, handling, and checkout of the missile. The missile components would arrive approximately 3 weeks before launch.

The MLP would accommodate needed range support systems such as communications relays (command and control), data collectors (telemetry), and tracking systems (infrared or optical). It would also provide a safe shelter for personnel engaged in the mission.

Sea launches of target missiles would be accomplished using the MLP as a launch platform. The MLP would be towed by an ocean tug to appropriate launch locations to support the launch of a target missile.

The MLP (figure 2.1.2-3) is a converted U.S. Navy LPH-10 helicopter carrier, retrofitted to allow for missile storage and launches. It is currently berthed in Concord, California. Target launches from this mobile platform would follow the same procedures as those for fixed ground-based target launches, except that launches would be made from the MLP. The MLP is free-floating and would not be anchored to the ocean floor during launching. The MLP would provide the ability to change launch azimuths and ranges of target missiles.

The MLP possesses large open and enclosed decks, good sea-state stability, onboard living quarters, and a deck-edge elevator. The maximum usable time of the MLP away from port is approximately 21 days, accommodating up to 100 personnel during operations. The MLP would carry fresh water using both existing ship holding tanks and bottled drinking water. Wastewater would be held in existing ship holding tanks when the MLP is within the regulatory distance from shore.

The MLP would be towed from its anchorage to perform launch preparations. The MLP could be positioned in the open ocean area near any alternative test range to provide a launch platform for ground-based target missile launches. To support an intercept, the MLP would be towed to a launch location in the open ocean. Final assembly and checkout of the target missile would be accomplished on the MLP. The MLP would be towed at slow speed during the launch of the target missile.
DIMENSIONS:

Figure 2.1.2-3

Representative Mobile Sea Launch Vessel, Alternative Target Launch Mode
2.1.3 IN-FLIGHT INTERCEPTOR COMMUNICATION SYSTEM DATA TERMINAL OPTIONS

The IDT provides communication links between the in-flight GBI missile and GMD Fire Control (GFC) components. IDTs are needed in close proximity to the GBI launch sites, and also at remote sites for each GBI flight test. Alternative IDT configurations that would support GBI flight tests may include a combination of fixed (land-based), relocatable (land-based), or mobile IDTs. The IDT is made up of the integration of the compound, facilities, antenna, communications node equipment, long haul communications, and embedded test capability.

2.1.3.1 Fixed In-Flight Interceptor Communication System Data Terminal

The fixed IDT would be contained in a building that is approximately 30.7 meters by 11.6 meters (101 feet by 38 feet) and would have a 5.5-meter (18-foot) diameter radome mounted on one end of the building (figure 2.1.3-1). The radome, which covers the antenna, would be inflatable. Lightning protection would be provided by lightning masts. Two 9-meter (30-foot) anemometer towers would be located at each site.

A hardened surface of 9.14 meters (30 feet) surrounding the IDT building would permit crane access for installing and, if necessary, replacing the radome or antenna. This area would also provide parking space for two utility vehicles and access for any other equipment that must be brought near the IDT.

An additional modular facility (or facilities) would be temporarily installed within approximately 30 meters (100 feet) of the IDT. This modular facility would be used to provide spare component and repair parts storage and workspace for technicians. There could be an environmentally protected entrance between the IDT and the modular facility. The modular facility would require communications and utility hookups including local commercial power. Interior water tanks and chemical toilets, inside the modular facility, would be frequently serviced and negate the need for water utility pipes and a septic tank system. The estimated size for these facilities would be approximately 186 to 465 square meters (2,000 to 5,000 square feet). An external diesel aboveground fuel tank with a fuel capacity of 3,785 to 5,678 liters (1,000 to 1,500 gallons) would supply fuel to the mission power backup generator, and both would be located near the IDT. This generator would be rated at 300 kW and would be housed in a 3.4- by 1.5-meter (11- by 5-foot) wide enclosure.

A 464.5-square-meter (5,000-square-foot) laydown area that would not interfere with the construction of the IDT buildings would be required. A perimeter fence and a 4.88-meter (16-foot) lockable service gate on the service road would be required for access onto the site. A patrol road is planned around the outside perimeter fence of the IDT compound. Access to the IDT compound would be via an all weather road from the nearest existing service road. There would be a similar road from the gate in the perimeter fence to the IDT building.

2.1.3.1.1 Fixed In-Flight Interceptor Communication System Data Terminal Construction

The IDT would be built on a concrete foundation designed to withstand local seismic events. An all-weather road to the IDT site would be required. A prepared surface perimeter, at least 4.5 meters (15 feet) wide around the building, would be required for crane access and parking for two utility and maintenance vehicles. Each IDT would result in approximately 3.2 hectares (8.0...
Fixed IDT

Mobile IDT

EXPLANATION
IDT = In-flight Interceptor Communication System Data Terminal

Figure 2.1.3-1

Conceptual Fixed and Mobile IDTs
acres) of disturbed area from construction activities within a fenced area. A perimeter patrol road at some locations would result in a total disturbed area of 5.9 hectares (14.6 acres). Local commercial electrical power would be the primary source of power for the IDTs at all locations, but each would also have onsite backup electrical generation provided by the mission power generator. Three fiber optic administrative telephone circuits would be required for voice communications and alarm monitoring. Power and fiber optic cable would be routed in existing right of ways where practicable. Construction would require approximately 35 personnel for 6 months.

2.1.3.1.2 Fixed In-Flight Interceptor Communication System Data Terminal Operations

The IDT is a radio transmitter and receiver that would only function during GMD exercises, missions, and test events. It is a Super High Frequency transceiver that would provide communications between the GFC and the in-flight GBI.

The IDT site would normally be unmanned except during acceptance/flight testing, preventative maintenance, corrective maintenance, and future upgrades by up to approximately 10 personnel. Power to an IDT site would be commercial power with backup power supplied by a dedicated generator at each site. Between generator testing and operations during power outages, it is estimated that the onsite backup generator would operate for approximately 200 hours per year.

Other than the diesel fuel and occasional maintenance of the diesel powered electrical generator and associated backup batteries, no hazardous materials or waste (except from chemical toilets) would be stored or generated onsite. One piece of equipment used on the system consists of a Klystron tube, which contains small amounts of beryllium. Should maintenance be required, a new tube would be brought onsite, and the replaced tube would be sent back to the manufacturer for repair.

2.1.3.2 Relocatable In-Flight Interceptor Communication System Data Terminal

A relocatable type of IDT provides the capability to remove, replace, and relocate the terminal should the need arise. The functions of the fixed and the relocatable IDTs are otherwise identical.

The IDT site would include modular facilities that are similar to the fixed facilities that are described for the fixed IDT in section 2.1.3.1. However the relocatable IDT would have a separate equipment shelter and radome shelter, rather than the combined building at the fixed IDT facility. The modular facility requirements, laydown area, power and manpower requirements, and operations, would be as described in section 2.1.3.1.

There would also be an IDT mounted on the SBX (see section 2.1.4). The SBX IDT would essentially be a modular design with a radome similar to the fixed IDT. Operational requirements would be similar to those of the fixed IDT, including a stable foundation, electricity, communications, utilities, security, lighting, and monitoring systems. Personnel would be transported to and from the platform by boat or helicopter.
2.1.3.3 **Mobile In-Flight Interceptor Communication System Data Terminal**

The mobile IDT (figure 2.1.3-1) would be a vehicle-platform-mounted system. Several vehicles would be required to accommodate the equipment and antennas. The IDT would require substantial redesign to operate as a mobile system. Since the mobile IDT would be an independent standalone system, no site preparation would be required. Separately transported Military Satellite Communication Systems (MILSATCOMs) would provide redundant communication. The primary advantage of the mobile IDT is its ability to move rapidly from site to site.

2.1.3.4 **In-Flight Interceptor Communication System Data Terminal Security**

The IDTs would be designed to meet physical security protection requirements in accordance with DoD 5200.8-R, *Physical Security Program*. They are System Secure Level A assets, and they would typically require protection 24 hours a day. Each IDT would require approximately 3.2 hectares (8.0 acres) of fenced area. Security lighting sufficient for camera observation at each IDT would also be required.

2.1.3.5 **Ground-Based Midcourse Defense Communications Network**

The GMD Communications Network is that portion of the GFC/C component that provides voice and data communications assets consisting of communication network manager resources, transmission equipment and circuits, cryptographic equipment, and local and wide area networks necessary to provide a dedicated, reliable, and secure GMD communication capability.

Components of the GMD Communications Network would be deployed to provide tactical system-like connectivity to all test articles of the ETR. Additional communications capability would also be implemented to provide functional connectivity to components of the IDTs, the GBI and target launch facilities, radars, and the GFC system. Communications would occur via a combination of existing and new communication cables (either fiber optic or copper) and COMSATCOM Earth Terminals.

**Commercial Satellite Communications**

The COMSATCOM Earth Terminal (figure 2.1.3-2) requires a footprint of approximately 0.1 hectare (0.25 acre) to accommodate the Earth Terminal and equipment. Primary power is from a commercial source with

![Figure 2.1.3-2](image)
backup power provided by generator. Communication cable to the launch control complex would be required. Equipment would be housed in a military van, a small building, or an existing adjacent facility if available. Security requirements for fencing include approximately 2.8 hectares (7 acres). The site requirements include a concrete base for the Earth Terminal, an all-weather road to the site, and a prepared surface around the site at least 4.6 meters (15 feet) wide.

**Communications Cable**

For communication among the components on the same installation, the ETR would maximize use of available communications assets, including cable. If communication cable is not available, new cable would be installed. Installation of new cable would be in existing conduit, if available. If not, new conduit would be constructed along rights-of-way. Where necessary, new conduit would require a route approximately 1 meter (3 feet) wide, buried to a depth of approximately 1 meter (3 feet) from the surface. A manhole and cover would be located approximately every 200 meters (600 feet) to allow access to the cables for maintenance and for future cable installations.

### 2.1.4 SEA-BASED TEST X-BAND RADAR

An SBX would support GMD integrated flight testing. It would exercise all midcourse sensor functions including weapon task plans, in-flight target updates, target object maps, and kill assessments. The SBX would support most ETR test scenarios, with additional support provided by the existing ground-based radar prototype (GBR-P) located at RTS at USAKA.

The SBX is made up of a seagoing platform on which an XBR has been mounted. This section describes the platform, the XBR, and the modifications required to the platform for the XBR to function correctly.

#### 2.1.4.1 Sea-Based Platform

The sea-based platform is an existing commercial platform manufactured by Moss Maritime of Oslo, Norway. The platform is a column-stabilized semi-submersible platform, with two pontoons and six stabilizing columns supporting the upper hull. The bare platform has a completely flat top deck on top of an enclosed double bottom structure. The structure has sufficient strength to support a deck load of 18,144 metric tons (20,000 tons). Table 2.1.4-1 provides the dimensions of the platform.

The sea-based platform is semi-submersible, meaning that it would have large ballast tanks that are evacuated to reduce draft for transit or portside use. When in position for testing, the tanks would be flooded, which both increases the displacement and lowers the center of mass, significantly reducing vulnerability to surface weather. Semi-submersibles can be anchored in up to 1,500 meters (5,000 feet) of water. Figure 2.1.4-1 shows an artist’s concept of the XBR and sea-based platform.

2.1.4.2 X-Band Radar

The XBR would be a multifunction radar that would perform tracking, discrimination, and kill assessments of overflying target missiles. The XBR would use high frequency and advanced radar signal processing technology to improve target resolution, which permits the radar to discriminate against various threats. The XBR would provide data from the mid-phase of a target missile’s trajectory and real-time in-flight tracking data to the GFC. The XBR would be mounted on a 27-meter (90-foot) diameter antenna mount track support cylinder housed in a 31-meter (103-foot) base diameter radome. Total height of the SBX above the water line including the XBR radome would be approximately 76.3 meters (250 feet) at transit draft. The XBR would have either a 65 percent populated array (approximately 39,000 elements) or a fully populated array (approximately 60,000 elements) to support the planned testing.

The XBR transmit/receive radiofrequency (RF) emission pattern would be a narrow beam (several meters diameter at 25 kilometers [15.5 miles]) with most of the energy contained within the main beam. Each main beam would consist of a series of electromagnetic pulses. The main beam would be able to provide near hemispherical coverage; i.e., 360 degrees in azimuth. At no time would the main beam be directed at the ground or water surface. Lesser amounts of energy would be emitted in the form of grating and side lobes in the area around the main beam. The main beam would have a lower limit of 10 degrees above horizontal for calibration and maintenance testing while at the Primary Support Base. The side lobes that reach the ground would be far removed from the main beam and would not contain sufficient energy to present any type of RF emission hazard.

Potential issues associated with electromagnetic radiation (EMR) are related to aircraft, electroexplosive devices (EEDs), communication and electronics equipment, and personnel safety. Figure 2.1.4-2 shows the SBX Radar Potential EMR Interference Areas, and table 2.1.4-2 lists the EMR potential interference distances.
Note: Only a portion of the potential interference distances are shown. The potential interference could be 360° around the SBX radar.

EED = Electroexplosive Device—a device in which electrical energy is used to initiate an enclosed explosive, propellant, or pyrotechnic material

It should be noted that at the Primary Support Base, even at the lower operating limit of 10 degrees, the altitude of the main beam would be well above the surrounding area as shown in Table 2.1.4-3.

To ensure public safety from potential EMR effects, an EMR/electromagnetic interference (EMI) study is currently underway for each potential operating area. This study would then support an application for spectrum certification and frequency allocation.

</table>
Civilian aircraft must be hardened or protected from EMR levels up to 3,000 volts per meter (V/m) (peak power) and 300 V/m (average power) as mandated by the FAA by Notice 8110.71, *Guidelines for the Certification of Aircraft Flying through High Intensity Radiated Field Environments*. The SBX would not exceed the 3,000 V/m peak power threshold. The average power threshold is based upon reducing the time of exposure of aircraft avionics (electronic equipment) to High Intensity Radiated Fields in order to preclude shortening the life of the aircraft avionics. Therefore, the concern is not interference but is a reduction in the life of the aircraft avionics.

For some operating areas, following coordination with the FAA, a high-energy radiation area notice may be requested from the FAA to be published on aeronautical flight information charts. As shown in table 2.1.4-2, based on modeling of the 65 percent and fully populated XBR, the FAA standard for average radiation exposure to aircraft could be exceeded out to a distance of 12.1 kilometers (7.5 miles) from the 65 percent populated radar and out to 19 kilometers (11.8 miles) from the fully populated radar. The potential high-energy radiation area for the XBR would therefore extend out to 12.1 kilometers (7.5 miles) and 19 kilometers (11.8 miles) for the 65 percent and fully populated radar. However, based on the spectrum certification and frequency allocation process, the high energy radiation area would be modified to fit existing airport and airspace requirements. Before operation of the XBR during individual tests, the FAA would provide notice to affected airports and aircraft through a Notice to Airmen (NOTAM).

EEDs are used for a variety of applications from the release of ordnance from the wing of an aircraft, for automatic fire extinguishers on aircraft, for pilot ejection seats, and even for the release of air bags on automobiles. An electrical current sufficient to initiate the EED can be induced by exposure of the device to an electromagnetic field. Thus, high levels of EMR can inadvertently initiate the device. Energy from EMR may also cause the EED to become inactive (a phenomenon known as dudding).

EEDs on aircraft in flight could be illuminated by the mainbeam of the SBX. As shown in table 2.1.4-2, based on modeling of the 65 percent and fully populated XBR, EEDs on aircraft in flight could be illuminated by the mainbeam of the SBX out to a distance of 4.8 kilometers (3 miles) from the 65 percent populated radar and out to 7.5 kilometers (4.6 miles) from the fully populated radar. Software controls and coordination with military and commercial aircraft controllers would eliminate this potential hazard. The power coming off of the grating lobes and side lobes of the SBX could illuminate EEDs on the ground. However, the potential radiation hazard would be limited to less than 10 meters (33 feet) in front of the radar, which includes a portion of the main deck of the SBX. Therefore EEDs on the ground, including those associated with airbags in vehicles, would not be affected.

The proposed SBX operates within the 8,000–12,000 MHz frequency band, commonly referred to as the X-band. RF interference is most likely to occur when two pieces of communications-electronics equipment are operated within the same frequency band. Therefore, equipment whose frequencies fall within the X-band is most likely to be affected by the SBX. Some examples of X-band communications-electronics equipment include airborne weather radars, fire control radars, and bomb/navigation radars. Garage door openers are well below this frequency and would not be affected. Interference is also possible to systems that operate in harmonically-related frequency bands. Harmonic frequencies include those frequencies that are integer multiples of the operating frequencies. Systems that operate in harmonically-related
frequency bands include airport surface detection equipment and broadcasting satellite service. Personal home satellite systems would not be affected.

Systems that operate outside of X-band and the harmonically-related frequency bands could be subject to interference due to high power effects from the SBX. High power effects typically occur in receivers that are located close to high power transmitters. The accepted levels for high power effects are 1 mW/cm² for military equipment and 0.1 mW/cm² for civilian equipment. At power levels below these thresholds, it can be reasonably assumed that high power effects are not likely to occur. At power levels above these thresholds, it cannot be stated with certainty that high power effects would occur, only that they are possible. Under proposed SBX operating conditions, full power operation would involve tracking objects in space with the beam pointed up and constantly moving. The beam would not remain stationary for any appreciable period of time; thus, the odds of interference from high power effects with any electronic equipment on the ground would be slight, 1/1000000 or 0.0001 percent of the time (roughly 1/10 of a second per day). The effects would not damage any electronic equipment and would last for less than a second, should this occur.

Under proposed SBX operating conditions, full power operation would involve tracking objects in space with the beam pointed up and constantly moving. The beam would not remain stationary for any period of time, and software controls would not allow a full power beam to come in contact with any personnel, on the platform or on land. Two separate, redundant computer systems would monitor all emission energy levels at locations around the radar to assure safe exposure levels are maintained. Similar software controls have been effectively used on the large X-band radar currently operating at Kwajalein Island in the Republic of the Marshall Islands.

2.1.4.3 Assembly and Retrofit Operations

The sea-based platform would be retrofitted at an existing shipyard on the U.S. Gulf Coast. It is possible that some retrofit operations could be completed at a shipyard on the U.S. west coast following transit from the Gulf Coast shipyard. The platform would initially be moored at a shipyard in Brownsville, Texas. After arrival at the shipyard, the platform would be outfitted with a variety of subelements that would allow it to function as a self-propelled seagoing platform. These modifications would include installation of the thrusters and preparation for the radar assembly installation. Upon completion of the ship modifications, the vessel would sail to Corpus Christi, Texas, for installation of the radar assembly. The subelements are divided between the facilities requirements and the XBR payload. Table 2.1.4-4 lists the various subelements.

The Radar Support Structure (RSS) and Drive Platform Control System would be assembled at the shipyard with its materials being transported either by truck or barge. The RSS and the Drive Platform Control System would be fully assembled on a concrete slab (existing or new depending on the shipyard selected). They would then be barged to the platform and lifted into place and installed on the top deck of the platform. At the fabrication site, low power calibration of single elements and subarrays plus low power radiation for systems checkout before integration on the platform would be performed. Full power emissions are defined as emissions from all elements in the array and occur during all other calibration, tracking, and mission tasks.

A full navigation suite would be provided with a high degree of automation to minimize the size of required marine crew. The SBX platform would be self-propelled by four steerable 3.4-megawatt (MW) electrically driven thrusters, which extend below the bottom surface of the platform's pontoons. While in open water, two thrusters would effectively propel and maneuver the SBX without assistance. In port, the SBX would be towed and assisted with at least two tugboats.

The SBX platform thrusters would be a retractable type. While the thrusters are extended, the draft of the SBX platform would be approximately 15.2 meters (50 feet). The retractable thrusters can be lifted into the pontoons to reduce the draft of the platform to approximately 10.7 meters (35 feet), allowing it to enter deep ports.

Crew member accommodations would be for 50 people, which currently include approximately 20 marine crew members and 30 GMD mission support personnel. In addition, there would be sufficient berthing, accommodations, and lifesaving equipment to support an additional 50 people onboard on a temporary basis to support testing.

Communication systems and an IDT would be mounted and positioned on opposite corners of the platform deck below the minimum depression of the radar beam. The SBX would use a single link, dual redundant IDT with two antennas. The two sets offer redundancy and avoid obscuration by the radar. There would also be two COMSATCOM terminals with two antennas each for a total of six antennas on the SBX.
2.1.4.4 Integrated Platform Testing in the Gulf of Mexico

The platform subsystem tests would be conducted in the shipyard. These tests would evaluate the performance of individual subsystems.

The initial sea trials would take place in the Gulf of Mexico. These tests are designed to ensure maneuverability and control of the vessel. Since these tests may run in parallel with the payload installation and checkout tests, mass simulators may be used to represent uninstalled portions during the stability and control evaluations. The emphasis would be on identifying and correcting problem operating conditions, such as vibrations that result from the installation of diesel and electric generators above the main deck or the vessel’s electric thrusters.

During the integrated platform testing, full power radiation for satellite and calibration device tracking would be performed. Electrical power requirements for the SBX platform and its various payloads would be approximately 21.8 MW. This would be supplied by eight 3.64-MW generators. Six generators of the eight would be used at any given time, and two would remain in reserve or as backup in case of failures or routine maintenance. Two of the four 3.4-MW thrusters would typically propel the SBX and consume 7 MW, with approximately 14.8 MW available for ship-board operations and powering the radar. The SBX would have a fuel capacity of approximately 3,100,000 liters (818,000 gallons). Approximate fuel consumption for transit and radar operation would be 54,800 liters (14,500 gallons) per day. Fuel consumption while hooked up to a primary support base pier would be 6,130 liters (1,620 gallons) per day.

2.1.4.5 Transportation of Sea-Based Test X-Band Radar from Assembly Point to Primary Support Base/Operations Area

The SBX would be self-powered, with a nominal cruising speed of approximately 15 kilometers per hour (8 knots) with two 3.4-MW thrusters. Due to the large “sail area” created by the XBR radome, actual cruising speeds would be affected by prevailing wind conditions. A 7-month test period would begin with the trip around South America to the Pacific Ocean. The Panama Canal cannot accommodate the width of the completed SBX platform. The transit time would create opportunities for testing as the vessel travels from the Gulf of Mexico to the Pacific test area.

Periodic test emissions for satellite and calibration device tracking would occur. In transit, the SBX would stop at predetermined locations, the FAA would provide notice to affected airports and aircraft through a NOTAM, marine traffic would be notified through a Notice to Mariners (NOTMAR), and then the SBX would conduct the test.

One or more escort ships may accompany the SBX during transit around South America and during testing.

2.1.4.6 SBX Basing Activities and Primary Support Base Alternatives

In between GMD test missions the SBX would return to a Primary Support Base (PSB) for crew rotations, resupply, and maintenance activities. The SBX would have a 10.7-meter (35-foot) draft. Because most harbors do not have the necessary depth to accommodate the SBX, it would not enter most port facilities after it leaves its assembly point in the Gulf of Mexico. If the SBX arrives at a location that cannot accommodate its deep draft, the vessel would moor or...
anchor offshore. Food, supplies, repair parts, and fuel would be delivered by supply ship. The distance that the SBX would remain offshore would be determined by several factors including water depth, transport capabilities of the support location, and radar testing requirements. Where port facilities have sufficient depth, the SBX would enter the port and utilize existing dockside facilities.

Although specific security guidelines have not been adopted for the SBX, it would likely utilize existing security zones, if they exist, at the PSB. If a security zone does not exist, then the SBX would likely utilize the same protection zone that applies to U.S. Navy vessels that are underway. Established by U.S. Coast Guard rule, this would include a 91.4-meter (100-yard) security exclusion zone around the vessel and a slow speed zone between 91.4 and 457 meters (100 and 500 yards) from the vessel. A security zone like this would likely be in effect as the SBX transits or when it is moored.

It is expected that the SBX would continue to operate the XBR while near or at the PSB. The operation would include system testing, calibration, and tracking of satellites. Radar emissions would occur in 15- to 20-minute periods totaling approximately 1 hour per day.

If existing facilities are not available or adequate at the PSB, some new storage and administration facilities would be constructed. If existing facilities are used, security upgrades, environmental controls for storage areas, fueling capability, ship gases handling facilities, computer networks, phone systems, and hazardous material storage and disposal may be added. Ongoing logistics and support operations such as resupply, fueling and maintenance, and crew/operator training would also occur at the PSB. Potential PSBs include Pearl Harbor, Hawaii; RTS; NBVC Port Hueneme, California; Naval Station Everett, Washington; Adak, Alaska; and Valdez, Alaska. In addition to supporting the ETR test activities, the SBX could also be used to support initial defensive operations capabilities being developed at Fort Greely, Alaska, and Vandenberg AFB, California. The activities described above for the SBX at the PSB would be identical for an SBX supporting initial defensive operations capability. The potential PSBs that would support initial defensive operations are the same as those listed above for the ETR. The evaluation of these PSBs to determine their capability to support initial defensive operations would include additional evaluative criteria. Section 2.4.4 describes the SBX PSB siting process and alternative locations considered.

2.1.4.7 SBX Test Activities
Numerous test flight scenarios would be conducted during the GMD ETR testing. Three SBX performance regions have been established to accomplish effective radar coverage for the test flights. Figure 2.1.4-3 shows the three performance regions that would be used. The SBX would operate within the approximate confines of one of the three performance regions based on the needs of the particular flight test scenario.

Approximately 10 to 12 days before a GMD test mission, the SBX would leave the PSB to travel to the designated performance region. During transit time, on-station time, and the return trip, the SBX would have certain preparation and mission activities. On-station GMD mission activities would include providing data from earlier phases of a target missile’s trajectory and real-time in-flight target tracking data to the GFC. During test activities the SBX would use its

multi-directional thrusters to remain in one location or travel at extremely slow speed while the radar is operating. Table 2.1.4-5 shows those pre-mission, mission, and post-mission activities that the SBX would perform. During test activities the SBX would likely utilize the same protection zone that applies to U.S. Navy vessels that are underway. This would include a 91.4-meter (100-yard) security exclusion zone around the vessel and a slow speed zone between 91.4 and 457 meters (100 and 500 yards) from the vessel.

Daily activities for the SBX would vary according to what phase of integrated testing the radar is in. Mission preparation activities would consist of satellite and sphere tracking, simulation runs, and operations and maintenance. The total amount of radar RF radiation per week would be approximately 5 to 6 hours. During actual GMD mission activities, the actual total duration of RF radiation would decrease to 3 to 4 hours per week. Table 2.1.4-6 shows the specific types of radar testing that would occur during all phases of SBX activities.

The SBX would operate in a manner similar to other large ocean-going vessels and could stop at ports other than the PSB to resupply. The SBX would utilize dockside facilities if available or anchor/maintain position offshore during the resupply activities.

2.1.5 TEST RANGE SENSORS AND SUPPORT INSTRUMENTATION

Sensor systems are used to acquire, record, and process data on targets and interceptor missiles to detect and track targets, direct defensive missiles, and assess whether a target has been destroyed. Sensor systems also include signal-processing components.

The signal-processing components receive the raw data collected by the sensor elements and process it, using computer hardware and software, into usable information such as target location, velocity, and attitude. These and other relevant characteristics can then be used to plan and control intercept engagements.
Sensor systems associated with interceptor missiles that may be used include existing ground-based sensors and newly developed or modified sensor systems. Sensors planned for use would be fixed or portable units. These units are routinely used to support missile flight tests. Potentially, other airborne sensors, ship-based sensors, and space-based sensors would also be used for surveillance and tracking support as part of these proposed GMD missile tests.

Instrumentation associated with the launch of a target missile would include radar, optics, and telemetry sites, and a launch control site. Figure 2.1.5-1 shows representative radar and telemetry equipment. Telemetry is provided through a real-time data acquisition system. Launch control is typically contained in a building, although mobile systems are also used (figure 2.1.5-2). Mobile systems would be brought to the selected location approximately 1 to 2 weeks before the launch date. In most cases the equipment would be removed within days after the launch.

2.1.5.1 Existing Range Sensors
2.1.5.1.1 Kodiak Launch Complex

There are currently no sensors permanently located at KLC. Sensors would be brought in for each launch, as required for a particular operational scenario.

AADC is currently building two Range Safety and Telemetry System vans. Once this system is proven, it would be used as the Range Safety and Telemetry System for launches from KLC. Additional instrumentation at KLC during a launch includes two mobile AN/FPS/MPS-36 class C-band radars, a mobile L-band surveillance radar, up to four mobile optical tracking systems, frequency surveillance antenna, and a transportable system to support mission preparation, data collection, processing, mission control, flight safety, and post mission data analysis.

2.1.5.1.2 Vandenberg Air Force Base

Existing range sensors at Vandenberg AFB include several range radars (AN/TPQ-18, AN/FPS-16, High Accuracy Instrumentation Radar, and AN/MPS-39) as well as fixed and mobile telemetry and optics equipment.
2.1.5.1.3 Reagan Test Site

Range sensors at RTS include the Advanced Research Project Agency Lincoln C-Band Observable Radar, and Long-range Tracking and Instrumentation. Both of these tracking radars are located on Roi-Namur at RTS. Additional radars include the Millimeter Wave Radar on Roi-Namur, Tracking and Discrimination Experiment Radar on Roi-Namur, and two MPS-36 C-band general-purpose instrumentation radars located at Kwajalein. The GBR-P is located on Kwajalein.

Telemetry sites located at Ennylabegan, Roi-Namur, and Gagan Islands include nine autotracking and three fixed antennas configured with multiple receivers and recorders. Optical sensors are also available at RTS.

2.1.5.1.4 Pacific Missile Range Facility

Range Control and the Operation Control Centers are in the Barking Sands operations area on the main base. Tracking and surveillance radars, data processing, and the communications network hut are included in the operations area.

The Makaha Ridge Site, 12.9 kilometers (8 miles) north of the PMRF main base at an elevation of 457 to 549 meters (1,500 to 1,800 feet), features tracking and surveillance radars, primary telemetry receivers and recorders, a Frequency Monitoring Station, and Electronic Warfare and networked communications systems.

Kokee Park, 19.3 kilometers (12 miles) north and east of the PMRF main base, is at an elevation of 1,036 meters (3,400 feet). This site has tracking radars, telemetry, ultra-high frequency and very high frequency communications, and command and control systems. Niihau, a privately owned island, features a remotely operated PMRF surveillance radar.

2.1.5.2 Test Event and Mission Sensors

2.1.5.2.1 Early Warning Radars

Eareckson Air Station Cobra Dane Radar
The AN/FPS-108 Cobra Dane Radar System collects and disseminates exoatmospheric, multiple-object intelligence data. The Cobra Dane is a large L-band, computer-controlled, phased array radar system with local wide- and narrow-band communication systems, and an operations and test complex. A modernization effort has extended the Cobra Dane’s operational life by 15 years and enhanced its performance to meet upgraded mission requirements. The upgrades include new hardware, including the signal and data processing system, receivers, displays, and software. Planned modification to the radar to support validation of the GMD operational concept would also support GMD ETR testing.

Beale Air Force Base Early Warning Radar
The Early Warning Radar at Beale AFB has a coverage that includes the West Coast of the continental United States. Planned modification to the radar to support validation of the GMD operational concept would also support GMD ETR testing.
Clear Air Force Station Early Warning Radar

The Early Warning Radar at Clear Air Force Station has a coverage that extends from the Arctic Ocean to the West Coast of the continental United States. Previously planned modification to the radar to support GMD deployment would also support GMD ETR testing.

2.1.5.2.2 Midcourse Sensors

Cobra Judy

Observation Island (Cobra Judy) is a U.S. Air Force shipboard phased array radar system. The Military Sealift Command is responsible for operating the ship, while the U.S. Air Force is responsible for operating the radar systems and overall mission accomplishment. Due to U.S. Air Force restructuring, the responsibility for mission accomplishment has been transferred to the Air Force Technical Applications Center, the U.S. Air Force Center of Excellence for providing national authorities with precision technical measurements to monitor treaty compliance.

Observation Island is a mobile platform that supports the Cobra Judy radar systems which are a national means for technical verification of foreign ballistic missile reentry systems. The instrumentation consists of the world’s largest ship-borne phased array radar, a parabolic dish-type radar and a telemetry system.

AN/SPY-1 Radar

The Aegis weapon system is a multi-mission weapon system employed on both cruisers and destroyers. The AN/SPY-1 radar, although designed primarily for the Anti-Air Warfare mission, has been modified to perform the ballistic missile detection and tracking as part of its new capability to perform Theater Ballistic Missile Defense. The AN/SPY-1 radar is capable of collecting ballistic missile track data during the boost and ascent phase of the missile. The radar would be integrated into the GMD Communications Network as an external-reporting sensor for the GFC/C.

Based on planned interceptor flight test target trajectories, AN/SPY-1 radar would establish the appropriate search fences to detect the target based on planned target launch points. On-ship radar mission operators would monitor the test control network to determine target launch time and status. Upon acquisition of the target, the radar would place the target under track and initiate track reporting.

TPS-X Radar

This radar is an aircraft transportable wide band, X-band, single faced, phased array radar system of modular design. The radar consists of five individual units: Antenna Equipment Unit, Electronic Equipment Unit, Cooling Equipment Unit, Prime Power Unit, and Operator Control Unit. The Antenna Equipment Unit includes all transmitter and beam steering components as well as power and cooling distribution systems. The Electronic Equipment Unit houses the signal and data processing equipment, operator workstations, and communications equipment. The Cooling Equipment Unit contains the fluid-to-air heat exchangers and pumping system to cool the antenna array and power supplies. The Prime Power Unit would be used to power the radar system or act as a standby power source if commercial power is available. The Prime Power Unit is a self-contained trailer with a noise-dampening shroud that contains a diesel
generator, governor, and associated controls, a diesel fuel tank, and air-cooled radiators. The Antenna Equipment Unit, Electronic Equipment Unit, Cooling Equipment Unit, and Prime Power Unit are housed on separate trailers interconnected with power and signal cabling, as required (see figure 2.1.5-3). Potential locations for the TPS-X radar include one site at KLC, previously disturbed areas at PMRF, and existing, previously analyzed sites at RTS and Vandenberg AFB.

**AN/FPQ–14 Radar**

The AN/FPQ-14 radar performs range tracking functions and is located at Kaena Point, Oahu, Hawaii. The radar is operated by the Air Force, 22nd Space Operations Squadron assigned to the 50th Space Wing, Schriever AFB, Colorado.

**2.1.5.3 Mobile Telemetry Systems and Mobile C-Band Radar**

The Mobile Telemetry Systems would consist of an 11-meter (37-foot) truck, two 5.4-meter (17.7-foot) antennas, and dual 10-kW generators. Figure 2.1.5-4 shows representative mobile telemetry equipment including the mobile telemetry and an instrumentation trailer. The mobile C-band radar would perform range tracking functions. A relatively level area or improved road would be required to site the systems. Intended operations would be to pull the telemetry and radar equipment into a prepared area and utilize a commercial power drop. Generators would provide a backup source of power. Uninterrupted Power Supplies are contained in each unit as an emergency backup if power is lost during a test flight.
Mobile Telemetry Systems and radar would be required to support the flight testing as a part of the proposed GMD action. Target telemetry and radar requirements include an up-range, mid-range, and down-range telemetry system to support launches. Figure 2.1.5-5 shows potential mobile telemetry locations.

Up-range telemetry and radar locations in Alaska that may be used include:

- KLC
- Pasagshak Point
- Homer
- King Salmon
- Adak
- Cordova
- Pillar Mountain

Mid-range telemetry and radar locations could include:

- Makaha Ridge, Hawaii (existing telemetry)
- PMRF, Hawaii (existing telemetry)
- Pillar Point, California
- Midway
- Bremerton, Washington

Downrange telemetry and radar locations could include:

- Wake Island (existing telemetry)

2.1.6 FLIGHT TEST PLANNING AND OPERATIONS

The target launch site would be occupied for approximately 2.5 months before a scheduled launch and 2 weeks after a launch. A typical 3-month launch cycle ramp-up would include 25 people during the first month, 55 to 75 people during the second month, and 110 to 150 people during the third month. Dual launch would include 25 people during the first month, 75 to 90 people during the second month, and 150 to 175 people during the third month. After a launch, approximately 50 personnel would immediately depart, and the remaining personnel would depart after launch site refurbishment.

For the GBI launch site, a typical launch cycle ramp-up would include 55 to 65 people during the first month, 100 to 130 people during the second month, and 205 to 260 people during the third month. Dual launch would include approximately 55 to 65 people during the first month, 120 to 150 people during the second month, and 235 to 300 people during the third month. After a launch, approximately 75 personnel would depart immediately.
Although Midway was an alternative site in the Draft EIS, MDA has determined that it is no longer a reasonable alternative and will not be a proposed site for ETR activities. The IDT on-board the SBX would perform the function that had been planned for Midway. The discussion of Midway has been retained in the Final EIS, however, in order to preserve the work that has already been performed.

EXPLANATION
Note: Although Midway was an alternative site in the Draft EIS, MDA has determined that it is no longer a reasonable alternative and will not be a proposed site for ETR activities. The IDT on-board the SBX would perform the function that had been planned for Midway. The discussion of Midway has been retained in the Final EIS, however, in order to preserve the work that has already been performed.

Mobile Telemetry Location Alternatives

Figure 2.1.5-5

Pacific Ocean

GMD ETR Final EIS

2-35
Interceptor and target missile contractor test personnel would be housed in motels, hotels, or mancamps in the vicinity and would commute to the launch site daily. U.S. Government and military test personnel may use military or commercial lodging if available.

2.1.6.1 Explosive Safety Quantity–Distances

An ESQD is established to account for the possibility of an unplanned event. Such an event would be characterized by either an explosion of the missile propellants or by the propellants burning without an actual explosion. An ESQD zone surrounding the explosives would be calculated in accordance with DoD Standard 6055.9, *Ammunition and Explosives Safety Standards*, and would consider factors such as the hazard classification of the explosive and actual test results for that explosive. The ESQD determination would be based on the equivalent explosive force of all propellant and pyrotechnic materials involved. Establishment of the ESQD zone represents DoD’s determination that areas outside the zone provide acceptable protection, and requires that areas inside the ESQD zone be cleared of non-mission-essential personnel for the entire period during which the explosives are present. Additionally, fire suppression, hazardous materials emergency response, and emergency medical teams would routinely be provided during the actual launch operations.

2.1.6.2 Typical Flight Test

The duration of a typical test flight would be approximately 20 to 30 minutes. Airspace surveillance procedures would last as little as 45 minutes, or as long as 3.5 hours if the test is delayed, after which it would be rescheduled. After launch, the missile would slowly gain speed in the first few seconds of flight, and then rapidly accelerate out of sight and earshot.

Approximately 1 minute into flight, the target missile would be at an altitude of approximately 19.3 kilometers (12 miles). The first stage would burn out and fall within the predicted booster impact area. The second and third stages would perform in similar manners, and the target missile would climb out of the atmosphere and into space. The target would reenter the atmosphere and decelerate until it is intercepted or impacts into the Pacific Ocean.

The tracking radar would acquire and track the target while the interceptor command and control system computes the best time to launch the interceptor missile. The interceptor missile would then be launched. Approximately 1 minute into flight, the interceptor would be at an altitude of 50 kilometers (31 miles) and approximately 65 to 80 kilometers (40 to 50 miles) downrange. The first stage would burn out and fall within the predicted booster impact area. The second and third stages would ignite, and the interceptor would continue toward the intercept point. After burnout, the second and third stages would fall into the ocean. The EKV would be deployed after third stage burnout. If the intercept is unsuccessful, the EKV would reenter the atmosphere and is anticipated to burn up on reentry. All booster stages would be programmed to land in predetermined and verified clear areas. Intercept altitudes could vary from approximately 100 to more than 250 kilometers (62 to 155.3 miles).

Intercept debris is the result of the collision between the target missile descending on its reentry trajectory and an interceptor missile moving horizontally or in a slight descent toward the target. For the most part, the target missile debris would continue downward, along the path toward its intended impact point. Similarly, the interceptor missile debris would continue along its path until gravity takes over and the pieces fall to Earth.
The most likely outcome of a successful intercept would be a few large pieces (tens of kilograms), more medium size pieces (less than a kilogram), and mostly small pieces of missile debris (less than 10 grams [0.35 ounces]). Some of the pieces would be small and heavy and have a low coefficient of drag. Others would be larger and lighter and have a high coefficient of drag. Each piece of debris would also have its own kinetic energy, which would be a function of its mass (how heavy it is) and its velocity (how fast it is). A heavy, fast piece of debris has more kinetic energy than a smaller, slower piece of debris. Air resistance, especially wind, has a large influence on where debris lands. A typical target missile reentry vehicle may weigh approximately 884.5 kilograms (1,950 pounds). A typical interceptor kill vehicle may weigh about 110 kilograms (240 pounds) at intercept. If an intercept is not successful, both the target and interceptor missiles would fall into the Pacific Ocean within designated clearance zones. Under normal conditions, missile components would not be recovered from the ocean.

2.1.6.3 Flight Test Clearance Areas

When a missile flight test is planned, there are certain areas where missile components and debris are expected to impact, called the booster drop zone and the debris impact area. These areas are verified safe as part of the test plan. There are other areas where debris may land if the test does not proceed as planned. These predetermined areas may be subject to the risk of mishap, such as an explosion or flight termination. Clearance areas are defined by the Range Safety Office to encompass the maximum probable distribution of debris or impact points of missile components. Figure 2.1.6-1 depicts typical GMD flight test clearance areas.

Each missile flight test event would be modeled using computer predictions of the behavior of the missiles. This modeling predicts what the missile may do in a number of situations where the missile, or parts of the missile, would fall to Earth. The models incorporate a number of variables such as the missile mass, velocity, trajectory, altitude, and descriptions of the environments that may affect the missile in flight, such as surface and high altitude winds.

Modeling that is done long ahead of the actual test would use average weather predictions. Modeling would be done on the day of test to verify safety under actual test conditions.

The Range Safety Office would communicate the extent of the clearance area, time, and date of the flight test, once they are defined, to the FAA, the U.S. Coast Guard, appropriate emergency management agencies, and local police jurisdictions for assistance in the clearance of designated land and sea-surface areas. Other areas under the flight path but not in a predicted impact or debris area would be monitored before the test event to determine the location of population or traffic. If the Range Safety Office determined that the population or ship traffic was in a safe position, the test would proceed.

Ground and range safety areas are developed to protect the public and private property against potential test mishaps. These safety areas are defined in terms of three scenarios: termination or explosion on the ground, either in the Missile Assembly Building or storage areas, or on the launch pad; termination of a missile’s flight shortly after liftoff; and termination of a missile’s flight after it has left the vicinity of the launch site.
Figure 2.1.6-1

Typical GMD Flight Test Clearance Areas

- Second Stage Booster Flight Path
- Third Stage Booster Flight Path
- Interceptor Flight Path
- Ballistic Missile Flight Path

EXPLANATION

EKV = Exoatmospheric Kill Vehicle
ESQD = Explosive Safety Quantity Distance
GBI = Ground-Based Interceptor

Not to Scale
2.1.6.4 Launch Hazard Areas

Before MDA would launch a missile, the Range Safety Office would determine if the missiles could be safely launched from the proposed location. To do this, the Range Safety Officer develops a Launch Hazard Area around the proposed launch site. The Launch Hazard Area is the area that could be affected by pieces of missile debris should an explosion occur just above the launch pad or in the event that the missile’s flight must be terminated in the early flight phase. This Launch Hazard Area is cleared of all but mission-essential test personnel during launch operations. Appendix C, Missile Launch Safety and Emergency Response, addresses Representative Launch Hazard Areas for each proposed launch location.

2.1.6.5 Flight Corridor

Another component of range safety is based on the possibility of a flight termination after the missile has exited the vicinity of the launch pad. A termination of this kind would occur in the event of an off-course flight. Mission planning and procedures would ensure the Flight Termination System would be activated in time for the flight vehicle to fall within its predicted flight corridor in the event of an off-course flight.

Should the missile head off course such that it is leaving its predicted flight corridor, the Range Safety Officer would activate the Flight Termination System. This would stop the flight vehicle’s thrust, and the missile pieces would then fall ballistically into the sea. This impact could occur outside cleared areas, but within a predetermined flight corridor.

2.1.7 FLIGHT TEST SAFETY

Once a test event is scheduled, there would be a standard sequence of notification and coordination procedures between the Range Safety Office and the agencies that would enforce the clearance of land, air, and sea areas. These areas are discussed below. The date and location of scheduled flight tests or training events would be published approximately 1 week in advance as described below for land, air, and sea areas.

Land Areas

Land areas that would need to be cleared are the Launch Hazard Area for each missile. Land areas would be cleared in cooperation with appropriate local law enforcement officials. Land areas would need to be cleared approximately 1 to 4 hours before a launch. As soon as the Range Safety Officer determines that the area is safe, the Launch Hazard Area could be reoccupied.

A Notice of Intent to clear certain land areas for safety reasons would be published in the local newspapers and broadcast in the local news media. The boundaries of Launch Hazard Areas would be posted with notifications. The areas would be closed approximately 1 to 4 hours before the planned launch and guarded to ensure they remain clear of non-mission personnel.

Airspace

FAA-controlled airspace is that in which most commercial aviation operates; that is, airspace up to an altitude of 18,288 meters (60,000 feet). Military Special Use Airspace may extend to higher altitudes, depending upon the individual restricted or warning area. The missiles involved in these GMD flight tests rapidly climb through this airspace and follow trajectories
high above this airspace. FAA-controlled airspace that would be affected includes airspace above the Launch Hazard Area for both the interceptor and the target launches, airspace above the booster drop zones, airspace above the predicted debris impact zone, and airspace above the predicted interceptor missile and target reentry vehicle impact zones if there is not an intercept.

Debris modeling for the day of test would predict the dispersion and linger time for test impact debris. Linger time is the time it would take for debris as small as 1 gram (0.04 ounce) to fall to Earth given the weather conditions at the time. Such small debris is important because it could be ingested into aircraft engines in flight, causing them to fail. This debris dispersion area may also have to be cleared of aircraft for some time after an intercept. Airspace would need to be cleared in advance of a planned test event to allow sufficient time to ensure that it is indeed clear; this would be approximately a half-hour before test launch. As soon as the Range Safety Officer determines that the area is safe, the airspace could be reoccupied. It could be as long as 2 to 4 hours before a debris dispersion area is declared clear.

The FAA would publish a NOTAM to avoid certain airspace areas for safety reasons. Conditions that are expected to exist for an extended period of time are reported in a Flight Data Center or NOTAM, and are published in the next biweekly NOTAM publication. The boundaries of Launch Hazard Areas would be posted with notifications, and range radar and aircraft would patrol the airspace to ensure that it is clear of aircraft before each flight test.

**Sea-Surface Areas**

Sea-surface areas that would have to be cleared include the Launch Hazard Area that extends over water, the predicted booster drop zones, the predicted debris impact zone, and the predicted impact zone for the interceptor missile and reentry vehicle. Sea-surface areas would be cleared with the cooperation of the U.S. Coast Guard. Sea-surface areas would need to be cleared in advance of a planned test event to allow sufficient time to ensure that it is indeed clear; this would be approximately 4 hours before test launch. As soon as the Range Safety Officer determines that the area is safe, the sea-surface areas could be reoccupied.

The Coast Guard would publish a NOTMAR to clear certain sea-surface areas for safety reasons. A Notice of Intent to clear certain sea-surface areas for safety reasons would be published in local newspapers, broadcast in local news media, and distributed to commercial fishing and tourist boating trade associations. Subject to the conditions of appropriate Memoranda of Agreement, U.S. Coast Guard officials would close the sea-surface area(s) up to 4 hours before the planned launch and then survey them to ensure that they are clear of ships or watercraft. Typically, U.S. Coast Guard vessels and range safety aircraft would patrol the area to ensure that it is clear of ships or watercraft.

Each missile in a flight test is tracked by a variety of sensor equipment to determine exactly where the missile is at all times during the flight. This tracking provides useful data to the program to satisfy test objectives as well as a range safety tool. The Range Safety Officer uses the real-time tracking capability, linked with the predictive modeling capability, to predict at any moment in the flight where the missile may land if thrust were terminated at that moment. This prediction is called an instantaneous impact point. Should a missile veer from its predicted flight path, the impact point predicts where it would fall. If the missile is predicted to leave the flight corridor or clearance areas, the Range Safety Officer would terminate the flight.
2.1.7.1 Post-Test Clearance Release

After completion of a missile flight test, the clearance areas would be released, or allowed to be re-entered. The Range Safety Officer would release the clearance areas as soon as he or she was assured that any hazardous aspect of the test was completed. Residual hazardous concerns may be gases from missile exhaust, presence of hazardous debris, debris still falling after an intercept, or other potentially dangerous consequences. Notification would be by radio, telephone, or computer to aviation and maritime authorities.

2.1.7.2 Debris Recovery

Following a successful intercept, debris would not normally be recovered from the Pacific Ocean. Potential debris from Air Launch Targets could include the target impact debris, pallet, and parachutes. Pallet debris could include metal fragments. The pallet and associated debris impacting the open ocean would sink and would not be recovered.

Recovery of missile and missile components after unsuccessful launches would be conducted in accordance with all applicable range procedures. If required, debris recovery may involve the use of helicopters and off-road vehicles. If the potential exists to disturb biological or cultural resources during debris recovery activities, recovery efforts would be coordinated with applicable range representatives and agencies to develop appropriate mitigation measures to avoid impact to sensitive resources and to restore natural areas as necessary following debris recovery efforts. After a successful launch, ground equipment would be parked and the site secured.

2.1.7.3 Mishap Response

Mishaps are, by definition, unplanned events, but they are not unforeseen. The Range Safety Officer would anticipate mishaps and plan responses ahead of time. These response plans both minimize the potential harm and speed recovery from the mishap. Flight termination is accomplished by stopping the propulsive thrust of the rocket motor. This is done by splitting the motor casing with a linear-shaped explosive charge or blowing open thrust ports, which releases the compression on the burning fuel. The linear-shaped charge or thrust ports are activated by a redundant Flight Termination System using radio signals from the Range Safety Officer. When thrust is terminated, the missile pieces continue along the current flight path and fall to Earth under the influence of gravity. Mishap scenarios and their consequences are described in chapter 4.0. Each launch location has an emergency response plan that includes the appropriate response to a launch-related mishap as described in appendix C.

2.1.8 FLIGHT TEST EXAMPLE SCENARIOS

As part of the alternatives for implementing the Proposed Action, interceptors launched against targets may originate from KLC, Vandenberg AFB, or RTS. Target missiles launched as a part of this ETR program may originate from KLC, Vandenberg AFB, PMRF, RTS, or from the MLP sea launch, or from an air launch platform in the Pacific region. All missile intercepts would occur over the Pacific Ocean. In the event the interceptor misses the target, the interceptor and target missiles would land in the Pacific Ocean. Under normal conditions, missile components would not be recovered from the Pacific Ocean.

Several examples of interceptor and target missile flight test trajectories are presented here to illustrate representative testing events that could occur as part of the GMD ETR test schedule (figures 2.1.8-1 through 2.1.8-6). These examples are meant to show representative GMD flight
Scenario 1: Target Launch from Vandenberg Air Force Base, Intercepted from Reagan Test Site

**Figure 2.1.8-6**
tests that could be conducted as a part of this Proposed Action; they are not meant to be inclusive or exclusive of other testing possibilities or launch trajectories.

The footprints displayed for debris represent the area within which all pieces of debris equal to or larger than 1 gram (0.04 ounce), 1.43 kilogram-meters (11 foot-pounds), and 9.9 kilogram-meters (76 foot-pounds) would fall. The 1-gram debris is the minimum for potential impacts to aircraft; 1.43 kilogram-meters (11 foot-pounds) is the lower limit for personnel injury; and 9.9 kilogram-meters (76 foot-pounds) is the level for personnel fatality (Range Commanders Council, Range Safety Group, 2002). If the interceptor misses the target it would burn up upon reentry. The target reentry vehicle would continue on its trajectory and land in the open waters of the Pacific Ocean. The appropriate Range Safety Officer would review test scenarios to ensure the interceptor kill vehicle and target reentry vehicle would not impact land areas should they miss.

2.2 NO ACTION ALTERNATIVE

Under the No Action Alternative, the GMD ETR would not be established, and interceptor and target launch scenarios would not be fully tested under operationally realistic conditions. All existing launch areas and other support facilities would continue current operations for GMD and other mission activities as described in the following paragraphs. Use of mobile GMD test elements is also described.

2.2.1 LAUNCH SITES AND OTHER SUPPORT FACILITIES

Kodiak Launch Complex

In defining the No Action Alternative at KLC, there are two decision points to be made by two different agencies (MDA and FAA); thus, there are two possible No Action Alternatives for this location.

The first is the MDA’s No Action Alternative, in which the GMD ETR would not be established. For KLC, this would result in a continuation of the status quo through September 2003 with up to nine launches occurring per year from the facility. The current launch site operator license for KLC expires in September 2003. At that time, it is possible that the FAA would renew the KLC launch site operator license to continue launch operations. Under the new KLC license, it would be possible for the MDA to conduct launches that meet the conditions of the KLC license. Selection of the MDA’s No Action Alternative would not preclude launches from the KLC. However, the activities associated with the ETR would not be conducted as described in this EIS.

If the FAA renews the launch site operator license for KLC, the AADC would continue launching various commercial and military launch vehicles from KLC. As shown in figure 2.1.2-1, several launch vehicles have been proposed for use and several others have already been launched from KLC. These launch vehicles are similar in size or larger than those included in the Proposed Action, and have similar potential environmental impacts. The Strategic Target System missiles launched from KLC would support GMD testing.

Under the second No Action Alternative by the FAA, the AADC’s launch site operator license, which permits them to operate KLC for the purposes of conducting launches, would not be renewed. In the absence of any other arrangement, launch activities at KLC would be discontinued. The AADC currently holds a 30-year renewable Interagency Land Management
Assignment from the Alaska Department of Natural Resources. If launch activity were discontinued at KLC, AADC would coordinate with the state to determine a proposed future use for the land. It is possible that the facilities and equipment at the site would be used for other government purposes or handled as government surplus (e.g., sold) as described in the FAA’s 1996 EA for KLC.

The lands on Kodiak Island at Narrow Cape have previously been considered for other development activities, such as prisons, schools, and other facilities. The site is located on one of the few improved roads on the island, and would be available for development for other purposes if AADC were no longer licensed to conduct launches.

For purposes of the analysis in this EIS, the FAA’s No Action Alternative covers only the discontinued use of KLC, and does not specifically include any decommissioning or remediation activities that may be associated with the discontinued use of the facility.

**Midway**

No GMD-related test activities would be conducted at Midway.

**RTS**

RTS supports testing for a variety of ballistic missiles and sensor test activities. Missile flight test activities would continue at RTS, and GMD would continue to use the Meck Island launch complex for single and dual launches of GMD missiles, including GBI missiles. The existing range radars, including the GBR-P, and the existing IDT would continue to provide GMD missile test program support.

Previous environmental documents have analyzed potential impacts and mitigations associated with launching 12 to 28 strategic missiles per year from Meck. Other missile defense test programs at RTS may include the Theater High Altitude Area Defense (THAAD) missile system.

**PMRF**

PMRF supports a wide variety of Fleet Training, Land-Based Training, and Test and Evaluation Activities. Fleet Training includes missile operations, air operations, gunnery, bombing, mining, electronic warfare, undersea warfare, and submarine operations. Land-based training includes solid and liquid propellant aerial target and missile launches, electronic warfare and countermeasures, radar, optical, telemetry, and communication systems operations, and troop exercises. Test and Evaluation activities include torpedo, torpedo defense, submarine and periscope detection, submarine systems, anti-submarine warfare, ship-defense systems, and land sensors.

Based on previous environmental analysis and current agreements, the Strategic Target System missile could be launched up to four times per year to support GMD or other missile test related programs. Additional missile tests at PMRF may include the THAAD missile system, Sea-Based Midcourse Defense, and various Fleet Training exercises such as the Rim of the Pacific exercise.
Vandenberg AFB

Vandenberg AFB typically supports approximately five Minuteman or Peacekeeper launches per year from northern Vandenberg AFB launch sites. Based on previous environmental studies and a Letter of Authorization with the National Marine Fisheries Service, up to 10 Minuteman and Peacekeeper launches per year could occur from northern Vandenberg AFB launch sites. GMD target missiles and GBI booster verification missiles would be included in this number. Approximately three GMD target launches and two GBI booster verification launches would occur per year from north Vandenberg AFB. However, GBI booster verification launches would not include intercepts of target missiles over the ocean.

Eareckson Air Station

Existing IDT, MILSATCOM, and the Cobra Dane Early Warning Radar would continue to be utilized at Eareckson Air Station.

2.2.2 MOBILE GMD SYSTEM ELEMENTS

Mobile Telemetry and Radar

Mobile telemetry and C-band radar would continue to be used as required to support target missile launches from KLC.

TPS-X Radar

The TPS-X radar would continue to operate at either RTS or Vandenberg AFB in support of ongoing MDA test activities.

AN/SPY-1 Radar

The AN/SPY-1 radar, although designed primarily for the Anti-Air Warfare mission, has been modified to perform ballistic missile detection and tracking as part of its new capability to perform Theater Ballistic Missile Defense. The Aegis ship would be positioned at various locations in the Pacific to provide missile tracking support during various MDA test activities.

Cobra Judy

Observation Island (Cobra Judy) is a U.S. Air Force shipboard phased array radar system. Cobra Judy would continue to operate in support of ongoing MDA test activities.

SBX

The SBX would not be built and operated in support of the GMD ETR. Initial testing of the SBX in the Gulf of Mexico would not occur, nor would there be a need for a port facility in the Pacific Region to support the SBX.

2.3 PROPOSED ACTION

This section describes the locations and components necessary for implementing each of the Proposed Action alternatives listed in table 2.0-1. Each alternative includes the components described in section 2.1 located at various sites that provide maximum test effectiveness. For analysis purposes in this EIS, three alternative test architectures have been identified based on
developing additional interceptor launch capability at (1) KLC, (2) Vandenberg AFB, and (3) both KLC and Vandenberg AFB. Each alternative test architecture would include common GMD test components consisting of GBIs, target missiles, IDTs, the SBX, and other sensors and instrumentation.

2.3.1 ALTERNATIVE 1
Alternative 1 includes the following components and locations:

- Single and dual GBI launches from KLC and RTS
- Single and dual target launches from KLC, Vandenberg AFB, and RTS
- Single target launches from the PMRF
- Target launches from mobile sea or air platforms
- Construction of two GBI silos or one GBI launch pad, and an additional target launch pad that could accommodate GBI launches if needed, and associated support facilities at KLC
- Target pad modifications at KLC and RTS
- COMSATCOMs at KLC, Midway, and/or sea-based
- Site preparation and operation of TPS-X radar at KLC or PMRF, or use of existing TPS-X at RTS or Vandenberg AFB
- Construction of an IDT at KLC, Midway, and/or sea-based
- Placement of small mobile telemetry units and mobile C-band radar at KLC and at one or two of the following locations: Pasagshak Point, Kenai, Homer, Soldotna, King Salmon, Adak, Cordova, and Pillar Mountain, Alaska; Pillar Point, California; Bremerton, Washington; Makaha Ridge and PMRF, Hawaii; Midway; and Wake
- SBX construction, Primary Support Base, and operation

2.3.1.1 Kodiak Launch Complex and Vicinity
As part of Alternative 1, the proposed GMD infrastructure for launching targets and interceptors would consist of the following:

- Two GBI launch sites, supporting facilities, and ancillary equipment to host two sets of Command Launch Equipment and all utilities and facilities to support operations
- Two target launch pads, supporting utilities, and infrastructure
- A Missile Assembly Building
- A Movable Missile Building
- Addition to the planned AADC Maintenance and Storage Facility
- Addition to the Launch Control Center
- Missile Storage Facility
- An IDT facility
- COMSATCOM equipment
- A new mancamp to support construction and operational personnel
- TPS-X radar
- An addition to the existing Narrow Cape Lodge adjacent to KLC
- Barge landing for large GBI components—adjacent to KLC

It is anticipated that the GBI and Target related construction periods would not occur at the same time.

**Existing and Proposed Launch Support Structures**

Existing facilities to be used, and in some cases modified, by GMD are listed in table 2.3.1-1. Proposed new facilities to support GMD are listed in table 2.3.1-2. The approximate area that would be affected during construction of the various components and facilities is listed in table 2.3.1-3. As shown in table 2.3.1-3, GBI related facilities include GBI access roads, GBI fenced area, GBI silos/Launch Pad, Mechanical/Electrical Building, Oxidizer Storage Building and road, entry control buildings, Maintenance Storage Building addition, Launch Control Center addition, existing lodge expansion, and a new mancamp. Construction for GBI-related components would require approximately 100 personnel for 12 to 15 months. Target-related facilities include target access roads, target launch pad, Movable Missile Building, Missile Assembly Building, Motor Storage Building and access road, existing lodge expansion, and a new mancamp. Construction for target-related facilities would require approximately 100 personnel for 12 to 15 months. Construction of the IDT would require approximately 35 personnel for 6 months.

</tr>
</tbody>
</table>

Since either GBI-related facilities or target-related facilities, or both, could be constructed at KLC, the areas are listed separately for each related facility. If both GBI- and target-related facilities are constructed, there would be an overlap of approximately 8.5 hectares (21 acres). Considering the overlap, the total potential disturbed area for GBI, target, COMSATCOM, mobile telemetry, TPS-X, and associated facilities would be approximately 26 hectares (64.2 acres).

The locations of the existing and proposed facilities are shown in figures 2.3.1-1 through 2.3.1-4.

Proposed Facilities

New GBI Silos
New GBI silos or a launch pad would be required at KLC. The silos are approximately 3 meters (10 feet) in diameter and 21 meters (70 feet) long (deep). The pad, if required, would be approximately 53.3 by 53.3 meters (175 by 175 feet). A Mechanical/Electrical Building would be constructed adjacent to the silos.

New Target Launch Pad
A new launch pad would be constructed to meet design specifications for the launch of target missiles. The pad could also support GBI missiles, although additional equipment would be required. The pad would be approximately 53.3 meters (175 feet) by 53.3 meters (175 feet).

Figure 2.3.1-4
New Missile Assembly Building

Although the current plans include use of the existing Integration and Processing Facility for missile assembly activities, the construction of an additional Missile Assembly Building will be evaluated in the EIS. The proposed Missile Assembly Building would be the location for processing launch vehicles and, for some configurations, mating of payloads to launch vehicles. The facility would be about 15 meters (50 feet) wide, 30 meters (100 feet) long, and 18 meters (60 feet) high, covering an area of 460 square meters (5,000 square feet). Exterior features would include the following:

- Paved access road and parking for staff vehicles and tractor trailers
- A paging and area warning system
- Wall-mounted sodium-vapor lighting
- Aircraft obstruction lighting
- A 500-kW diesel generator (maximum 146 liters [39.3 gallons] of fuel per hour)
- A 9,500-liter (2,500-gallon) storage tank for Number 2 diesel fuel
- A 59-square-meter (625-square-foot), 1.8-meter-high (6-foot-high) mounded absorption bed (buried 4,700-liter [1,250-gallon] septic tank)

The interior of the proposed Missile Assembly Building would contain a large, central working area with an overhead crane and a peripheral entry room, restroom, utility rooms, and an equipment airlock. Portable detectors would be used to monitor for hazardous vapors. Depending on the type of launch vehicle involved, fairing-enclosed payloads would be connected to the launch vehicles, and multi-stage launch vehicles inter-connected, in a horizontal position on carts. The integrated assemblies would be electronically tested. The facility would be designed for a 20-person capacity. Peak water demand and sanitary discharge would be approximately 2,400 liters (650 gallons) per day. The proposed Missile Assembly Building would be similar to the existing Integration and Processing Facility shown in figure 2.3.1-5.
New Movable Missile Building
The proposed Movable Missile Building (figure 2.3.1-6) would be a mobile structure used to enclose missile assemblies for transfer to the launch pad. The new facility would be approximately 12 meters (40 feet) wide, 21 meters (70 feet) long, and 33.5 meters (110 feet) high, and it would have doors at both ends of the structure. The structure would be mounted on rollers on steel rails imbedded in concrete foundations. The assemblies would be wheeled on carts out of the Missile Assembly Building and into the Movable Missile Building through abutting doorways. Detectors would be used to monitor for hazardous vapors. After closing doors and securing carts, a tractor would move the Movable Missile Building with target missile to the target launch pad or over the GBI silos or pad.

Once at the target launch pad, the target launch vehicle and payload would be lifted from the horizontal to the vertical position (figure 2.3.1-7) and would be enclosed in the Movable Missile Building until the time of launch, at which time the building would be moved away. External features would include the following:

- A 53-meter (175-foot) square concrete pad
- Steel-lined concrete ductwork to deflect launch-exhaust flame and accompanying noise toward the north
- A paging and a warning system
- Wall mounted sodium-vapor lighting
- Rail system between the new Missile Assembly Building and GBI silos or launch pads
- Aircraft obstruction lighting

Internal features would include vertically adjustable platforms for accessing various levels of the target missile and payload, a crane, clean work areas, utility rooms, and communications umbilicals to link the target missile to the Launch Control Center. Emergency power would be supplied from the Missile Assembly Building, and uninterruptible-power-supply batteries would serve critical loads. Portable detectors would be used to monitor for hazardous vapors.

Missile Storage Facility
The Missile Storage Facility would be approximately 30.5 meters (100 feet) wide, by 38.1 meters (125 feet) long, by 5.5 meters (18 feet) high. The Missile Storage Facility would have a perimeter fence.
Target Missile at Launch Pad

Figure 2.3.1-7
**Oxidizer Storage Facility**

An oxidizer storage building would be constructed in the vicinity of the existing hypergolic fuel storage building. The building would be approximately 5 meters (16.4 feet) by 5 meters (16.4 feet) with a security fence similar to the fence at the hypergolic fuel storage facility.

**Mancamp**

The proposed mancamp would be located on KLC property to the west of the Launch Control Center to house construction and operational personnel. The building would be approximately 50 meters (164 feet) wide, 90 meters (295 feet) long, and 10 meters (35 feet) high, with the capacity to house approximately 60 personnel. The mancamp would have perimeter fence. An additional alternative is an addition to the existing Narrow Cape Lodge mancamp. This addition would be approximately the same size as the proposed mancamp.

**Commercial Satellite Communications**

The COMSATCOM Earth Terminal (figure 2.1.3-2) requires a footprint of approximately 0.1 hectare (0.25 acre) to accommodate the Earth Terminal and equipment. Primary power is from a commercial source with backup power provided by generator. Communication cable to the launch control complex would be required. Equipment would be housed in a military van, a small building, or an existing adjacent facility if available. Security requirements for fencing increase desired acreage to approximately 2.8 hectares (7 acres). The minimal requirements include a concrete base for the Earth Terminal, an all-weather road to the site, and a prepared surface around the site at least 4.6 meters (15 feet) wide. KLC would require two COMSATCOMs for redundancy requirements. One existing COMSATCOM would be utilized and a new COMSATCOM would be constructed at one of the proposed IDT locations identified on figures 2.3.1-2, 2.3.1-3, and 2.3.1-4.

**Communications Cable**

For communication among the components on the same installation, the ETR would maximize use of available communications assets, including cable. If communication cable is not available, new cable would be installed. Installation of new cable would be in existing conduit, if available. If not, new conduit would be constructed along rights-of-way. Where necessary, new conduit would require a route approximately 1 meter (3 feet) wide, buried to a depth of approximately 1 meter (3 feet) from the surface. A manhole and cover would be located approximately every 200 meters (600 feet) to allow access to the cables for maintenance and for future cable installations.

**In-Flight Interceptor Communication System Data Terminal**

As described in section 2.1.3, the IDT could be a fixed or relocatable land-based unit. A fixed IDT would be contained in a building that is approximately 30.7 meters by 11.6 meters (101 feet by 38 feet) and would have a 5.5-meter (18-foot) diameter radome mounted on one end of the building (figure 2.1.3-1). The radome, which covers the antenna, would be inflatable. An external aboveground fuel tank would be located near the building. The mission backup power generator would be located adjacent to the IDT. This backup generator would be rated at 250 kW and would be housed in a 3.4- by 1.5-meter (11- by 5-foot) wide enclosure.

A relocatable IDT would require approximately the same area and have similar utilities requirements as a fixed IDT. Figures 2.3.1-2, 2.3.1-3, and 2.3.1-4 show the three alternative
sites for the IDT at KLC. Operations and security requirements would be as described in section 2.1.3.

**TPS-X Radar**
As described in section 2.1.5.2, the TPS-X radar is a transportable wide band, X-band, single faced, phased array radar system of modular design. The alternative site for IDT, located south of the existing Loran C Station, shown on figure 2.3.1-4, could also be used for the TPS-X radar. The TPS-X site would require 0.3 hectare (0.8 acre). The Prime Power Unit is a 1.5-MW generator that provides power to the radar during testing. Operation of the Prime Power Unit would require refueling operations. The fuel tank would be filled from a fuel truck, as necessary. Impermeable ground covering material and spill containment berms would be placed for containment of fuel during fueling operations. Spill control procedures that meet AADC’s approved SPCC, and spill control kits would be present at the site in the unlikely event of a fuel leak or spill.

The Cooling Equipment Unit is a closed system, and no discharges of the ethylene glycol solution are planned. However, because of the remote potential for leaks or spills during system hook-up, or the possibility of ruptured hoses or accidental disconnection, impermeable ground cover would be in place as was described for the Prime Power Unit.

EMR hazard exclusion areas would be established around the TPS-X radar antenna. The personnel exclusion area would extend for 150 meters (492 feet) in front of the radar. The FAA would be requested to establish a navigation warning advising aircraft to remain at least 1,500 meters (4,900 feet) from the TPS-X radar site. EEDs in the presence and shipping phase, such as a missile mounted on an aircraft, would need to be at least 800 meters (2,625 feet) from the radar. EEDs in the handling phase would need to be at least 400 meters (1,312 feet) from the radar due to potential sidelobe exposure. Figure 2.3.1-8 depicts these potential TPS-X radar radiation interference areas.

**Launch Complex Security**
It is assumed that testing would be on a campaign basis and the security for these tests would be on a similar basis. It is estimated that the security activities would occur for approximately 5 weeks for each campaign.

Security force personnel would be present at KLC during each campaign. There would be one Security Operations Center, located in the addition to the Launch Control Center, which would be shared with the KLC security personnel. This building would house the central program protection activities for the site and all operations equipment. Lights would be installed outside the building.
TPS-X Radar Radiation Interference Areas

Explanations:
- Aircraft - Main Beam Exposure
- EEDs in presence and shipping phase - (600 meter) - Main Beam Exposure
- EEDs in loading and handling phase - (400 meter) - Side Lobe Exposure
- Personnel - (150 meter) - Side Lobe Exposure

TPS-X = Transportable System Radar

Figure 2.3.1-8

GMD ETR Final EIS

2-64
A parking area would be established at the building for patrol and private vehicles. Additional roads may be needed depending on the site chosen for the building. Additional buried telephone and power lines would also be required to the building.

Up to three Access Control Facilities may be required that include one to the entrance of KLC and two other locations. These may be mobile or permanent construction depending on their location and overall utility. Wherever located, each Access Control Facility would require power for internal and external lighting. Parking and one portable restroom would be required per Access Control Facility.

The existing Intrusion Detection System would be expanded to include all critical buildings associated with the GMD operations. This would include the installation of additional intrusion sensors, lighting, closed circuit television, and a monitor for the sensors. These systems are common and are used at other sites used by the GMD.

Additional physical protection features may be constructed or placed to protect GMD assets. These may include, but are not limited to, fences, security lighting, bollards, tapered concrete barriers or similar devices, ditching and/or earth mounds, patrol roads, and observation tower(s).

During the operational day, security vehicles would be on patrol. At night, there would be additional vehicles in use as needed. Each vehicle would have radio equipment that would be in operation while on patrol. Normal patrols would be confined to existing roads. There would be occasions when these vehicles would be expected to go off-road.

Public Access Limitation

For safety reasons, the public would be denied access to KLC and the use of Fossil Beach for up to 1 day during any interceptor or target launch. It is anticipated that an Access Control Facility would be established at the entrance of KLC during a campaign to record vehicles entering and leaving the site. Additionally, beach access would be restricted for hours at a time during hazardous operations in accordance with the existing KLC safety plan. The beach could also be closed during times of heightened national security.

2.3.1.2 Midway—In-Flight Interceptor Communication System Data Terminal and Commercial Satellite Communications

Although Midway was an alternative site in the Draft EIS, MDA has determined that it is no longer a reasonable alternative and will not be a proposed site for ETR activities. The IDT on-board the SBX would perform the function that had been planned for Midway. The discussion of Midway has been retained in the Final EIS, however, in order to preserve the work that has already been performed. Under Alternative 1, an IDT and two COMSATCOMs, located in close proximity, would be required in a performance region located in the Pacific Ocean. Figure 2.3.1-9 provides the candidate IDT and COMSATCOM locations on Midway. Two of the potential sites include collocated telemetry, COMSATCOM, and IDT. There is also a third site that is COMSATCOM only. In addition, there is an existing COMSATCOM site that could be refurbished for GMD use.
Although Midway was an alternative site in the Draft EIS, MDA has determined that it is no longer a reasonable alternative and will not be a proposed site for ETR activities. The IDT on-board the SBX would perform the function that had been planned for Midway. The discussion of Midway has been retained in the Final EIS, however, in order to preserve the work that has already been performed.

EXPLANATION

- **Pacific Ocean**
- **Airfield**
- **Land**
- **Roads**

**Scale**

0  381  762 meters
0  1,250  2,500 feet

Note: Although Midway was an alternative site in the Draft EIS, MDA has determined that it is no longer a reasonable alternative and will not be a proposed site for ETR activities. The IDT on-board the SBX would perform the function that had been planned for Midway. The discussion of Midway has been retained in the Final EIS, however, in order to preserve the work that has already been performed.

Source: Camber Corporation, 2002 (modified); Ikonos Satellite, 2002 (modified).
As described in section 2.1.3, the IDT could be a fixed or relocatable land-based unit. A fixed IDT would be contained in a building that is approximately 30.7 meters by 11.6 meters (101 feet by 38 feet) and would have a 5.5-meter (18-foot) diameter radome mounted on one end of the building (figure 2.1.3-1). The radome, which covers the antenna, would be inflatable. An external aboveground fuel tank would be located near the building. The mission power generator would be located adjacent to the IDT. This generator would be rated at 250 kW and would be housed in a 3.4- by 1.5-meter (11- by 5-foot) wide enclosure. Dimensions are approximations only.

The COMSATCOM Earth Terminal (see figure 2.1.3-2) requires a footprint of approximately 0.1 hectare (0.25 acre) to accommodate the Earth Terminal and equipment. Primary power would be from the existing Midway power supply with backup power provided by generator. Equipment would be housed in a military van, a small building, or an existing adjacent facility if available. Security requirements for fencing include approximately 2.8 hectares (7 acres). The site requirements include a concrete base for the Earth Terminal, an all-weather road to the site, and a prepared surface around the site at least 4.6 meters (15 feet) wide.

Construction of the IDT and COMSATCOM would require approximately 35 personnel for a period of 6 months.

2.3.1.3 Ronald Reagan Ballistic Missile Defense Test Site

Under Alternative 1 the RTS would continue to be a launch site for GBIs. The following activities would continue at RTS:

- Launch of GBIs from Meck and use of existing IDT on Kwajalein
- Use of extensive range instrumentation
- Use of the GBR-P ground-based XBR
- Missile intercepts in the Broad Ocean Areas (BOAs) north and northeast of RTS

The existing Payload Launch Vehicle GBI silo could be modified to provide the capability to launch target missiles. The candidate GMD locations at Meck Island are shown on figure 2.3.1-10.

RTS is also a potential PSB location for the SBX. Although the piers at the RTS harbor do not offer adequate depth to accommodate the draft of the SBX, the vessel can enter the Kwajalein Lagoon and moor in a protected anchorage. A dedicated resupply vessel would not be required as RTS has a full complement of supply and fueling vessels. The mooring area would be approximately 5 to 6 kilometers (3 to 4 miles) north of the RTS harbor (see figure 2.3.1-11). The SBX would enter the lagoon either through Gea Pass on the west side of the atoll or at Mellu Pass on the north side. Both passes offer sufficient depth to accommodate the vessel. Mellu Pass, however, offers a much greater width for maneuverability. If entering at Mellu Pass (the preferred entry point), harbor officials at RTS have identified a likely transportation route to the mooring location called the Kwaj-Roi Highway. There are some obstacles (coralheads, shipwrecks), though, where avoidance would require navigation around and coordination with harbor officials. Personnel would be ferried to the SBX each day either by watercraft or helicopter.

Existing warehouse and administrative space at RTS is available to support SBX operations.

2-69
2.3.1.3.1 Existing Dual Ground-Based Interceptor Launch Capability

Single and dual launches of GBIs would occur from existing silos Com 1 and Com 2 on Meck. The existing GBI Missile Assembly Building, missile storage, maintenance and storage, and launch control facilities would also be utilized (table 2.3.1-4 and figure 2.3.1-10).

Target Missile Launch

Dual launches of target missiles would occur from a modified Payload Launch Vehicle GBI silo and a new launch pad, both on Meck. Existing GBI missile launch support facilities identified above would be utilized to support target missile launches.

Existing Instrumentation

Existing sensors and other instrumentation that would be used at RTS include range radars, the GBR-P prototype XBR, and telemetry instrumentation as described in section 2.1.5.1.3. The GBR-P would be upgraded through the addition of radar elements to the existing radar face and software upgrades.

2.3.1.4 Pacific Missile Range Facility

Under Alternative 1, the capability exists at PMRF to support the following activities:

- Launch of a single strategic target for intercepts from either RTS or KLC
- Use of existing range instrumentation to monitor target launch and intercept debris
- TPS-X radar on the Main Base or Makaha Ridge
2.3.1.4.1 Existing Single Target Launch

Up to four Strategic Target System missiles per year may currently be launched from the Kauai Test Facility (KTF) at PMRF. No new missile launch azimuths would be required for the Proposed Action. The current missile trajectories are toward the USAKA/RTS BOA and toward the BOA off the northwest coast of North America. The USAKA/RTS trajectory has been successfully used four times in the last 10 years. Northern trajectories would be implemented using current launch azimuths. Once over open ocean, the missile would then execute a turning maneuver (or series of turns) to bring it onto the desired flight trajectory. As such, the Proposed Action would not require new launch azimuths or the establishment of new special use airspace zones. Facilities required to support a target launch are listed in table 2.3.1-5.

</tr>
</tbody>
</table>

2.3.1.4.2 Existing Instrumentation

Existing sensors and other instrumentation that would be used at PMRF are described in section 2.1.5.

2.3.1.4.3 TPS-X Radar

As described in section 2.1.5, the TPS-X radar is a transportable wide band, X-band, single faced, phased array radar system of modular design. There are two alternative sites at PMRF for the TPS-X as shown on figure 2.3.1-12. The main base TPS-X site is also an alternative site for the THAAD Radar. At Makaha Ridge, the TPS-X would be set up on an existing disturbed area. The TPS-X site would require 0.3 hectare (0.8 acre). The Prime Power Unit is a 1.5-MW generator that provides power to the radar during testing. Operation of the Prime Power Unit would require refueling operations. The fuel tank would be filled from a fuel truck, as necessary. Impermeable ground covering material and spill containment berms would be placed for containment of fuel during fueling operations. Spill control procedures would be established in cooperation with PMRF, and spill control kits would be present at the site in the unlikely event of a fuel leak or spill.
EXPLANATION

PMRF = Pacific Missile Range Facility
MAB = Missile Assembly Building
STARS = Strategic Target System

PMRF Installation Boundary

Potential TPS-X Radar Sites

Pacific Missile Range Facility
Kauai, Hawaii

Figure 2.3.1-12
The Cooling Equipment Unit is a closed system, and no emissions of the ethylene glycol solution are planned. However, because of the remote potential for leaks or spills during system hookup, or the possibility of ruptured hoses or accidental disconnection, impermeable ground cover would be in place as was described for the Prime Power Unit.

EMR hazard exclusion areas would be established around the TPS-X radar antenna as shown on figure 2.3.1-8.

2.3.1.5 Vandenberg Air Force Base

Under Alternative 1 Vandenberg AFB would continue to be a launch site for GMD target missiles. The following activities would continue at Vandenberg AFB:

- Launch of single or dual target missiles
- Use of extensive range instrumentation
- Use of TPS-X radar

Vandenberg AFB functions as the test area for space and missile operations, and includes a network of tracking and data-gathering facilities (supplemented by instrumentation on aircraft) throughout California, Hawaii, and the central Pacific. Vandenberg AFB includes a large area of operation and the capabilities to perform a wide range of missile testing. Existing facilities that would be used at Vandenberg AFB are listed in table 2.3.1-6.

</tr>
</tbody>
</table>

Note: If LF-3 is used to support an initial defensive operations capability, then an additional silo would need to be identified to support a dual target launch. At such time as dual launch requirements are defined, additional environmental planning would be carried out as required.

2.3.1.5.1 Target Launch

Target missiles are currently launched from Launch Facility (LF) -6 and LF-3 in support of the GMD program (see section 2.3.2.1.2). Building 6816 would continue to be used for missile assembly and maintenance and storage. A dual launch capability would require minor interior modifications to some existing facilities.
2.3.1.6 Pearl Harbor, Hawaii

Pearl Harbor is a potential PSB location for the SBX. Pier Victor 3, located on the southeast tip of Pearl City Peninsula, has been identified by the U.S. Navy as the most likely area to support potential SBX activities. The pier is 135 meters (442 feet) long. It is currently supplied with potable water. Prior to November 2002, two types of jet fuel (which could be converted to supply marine diesel oil) were supplied to the pier. Additional work would be required to reestablish fuel service. Power lines run near the pier, allowing for relatively easy modifications to provide the platform with power. Structural augmentation would likely be required to support mooring and material handling operations. The pier is relatively secluded, and it would provide limited access and good security. New warehouses and administrative facilities in the same fenced compound as Pier Victor 3 could be constructed for SBX use. An alternative would be to lease existing administrative/warehouse facilities at an off-base location. If the SBX were to use Pearl Harbor as a PSB, the current plan would be to moor the SBX off of Barbers Point as shown in figure 2.3.1-13. A resupply ship would service the SBX, and personnel would be ferried to the SBX each day either by watercraft or helicopter. If an alternate mooring location is identified for Pearl Harbor, additional environmental planning would be performed.

2.3.1.7 Naval Base Ventura County Port Hueneme (California)

NBVC Port Hueneme is a potential PSB location for the SBX. It is located 97 kilometers (60 miles) northwest of Los Angeles and 80 kilometers (50 miles) south of Santa Barbara. The base itself covers more than 647 hectares (1,600 acres). Warehouse and administrative space is available for lease. An alternative would be to lease existing admin/warehouse facilities at an off-base location. The actual port is neither wide enough nor deep enough to allow the SBX to have pier-side operations. However, San Nicolas Island, located approximately 97 kilometers (60 miles) offshore (figure 2.3.1-14), provides an excellent mooring location. Situated within the Navy’s 93,240-square-kilometer (36,000-square-mile) sea test range, San Nicolas Island would also provide a large area of controlled air and sea space for SBX operations while in port. Mooring would probably be on the leeward side of the island, which is on the south/southeast side. Water depths there allow for mooring approximately 800 meters (2,625 feet) offshore. There is a fuel mooring site and undersea pipeline at San Nicolas Island that could support refueling operations. Naval Air Warfare Center, Weapons Division (NAWCWD) controls all air and sea area within the sea range as well as RF management. Both flights and commercial shipping either into or out of Los Angeles pass north or south of the sea test range unless permission is granted by NBVC officials. Flights out of Los Angeles pass either north or south of the sea test range.

San Nicolas Island has a 3,048-meter (10,000-foot) runway and its own power plant. San Nicolas Island is also fully integrated via fiber optics with NBVC Port Hueneme. Construction of a new pier on the island will be completed within 18 months. This pier would not support SBX pier-side operations, but would support ship-to-shore supply operations. Radar emitting at the mooring site is not anticipated to present any conflicts with current operations. Emission fans would be required to work around personnel and contractors living and working on the island, and the sensitive wildlife species found there.

2-76
2.3.1.8 Naval Station Everett (Washington)

Naval Station Everett is a potential PSB location for the SBX. It is homeport for the Abraham Lincoln Carrier Battle Group, which includes a carrier, three frigates, and three destroyers. The base consists of approximately 47 hectares (116 acres). Currently there is excess warehouse and administrative space available that could be used for the SBX. An alternative would be to lease existing administrative and warehouse facilities at an off-base location. The base has several piers to support the carrier battle group. Pier A has a 16-meter (54-foot) depth, which is used for USS Abraham Lincoln. This carrier is out of port approximately 6 months out of the year. The SBX would conduct pier-side operations at either Pier A or the adjacent Pier B. Figure 2.3.1-15 provides a general location of Naval Station Everett and the SBX location. Depths in the harbor would allow the SBX to submerse to operating levels if needed. Naval Station Everett is located relatively close and provides easy access to the Puget Sound main channel.

2.3.1.9 Adak, Alaska

Adak, Alaska, is a potential PSB location for the SBX. Adak is located in the Western Aleutian Islands, approximately 2,092 kilometers (1,300 miles) southwest of Anchorage. A naval base was established on the island when allied forces captured it in 1942. Before its closure in 1996 the population of Adak was about 6,000. The Adak Reuse Corporation is working to develop a community on the island by promoting new business developments. Adak Fisheries Development Council operates a seafood processing and cold storage plant on the island. Currently, there are approximately 250 personnel on Adak. Former government quarters rented out as individual units serve as lodging accommodations for visitors to Adak. The island also has a hotel, a grocery store, and more than 1,000 housing units each with electric, water, sewer, telephone, and cable television. Dining facilities are limited to two restaurants. Adak has two 2,377-meter (7,800-foot) paved runways with advanced navigation and weather systems as well. There are also the remaining facilities that were established as a part of the naval base, including a port. The Adak port facilities are primarily used by research ships, station work vessels, cruise ships, factory trawlers, and fishing boats. The Port of Adak maintains three cargo and petroleum piers. Docks have approximately 9 meters (30 feet) of draft at mean low tide. The proposed mooring location for the SBX would be in Finger Bay, a relatively deep and protected fjord located south of the main port. Figure 2.3.1-16 provides a general location of Port Adak and the potential mooring location at Finger Bay.

2.3.1.10 Valdez, Alaska

The Port of Valdez is a potential PSB location for the SBX. It is located at the upper end of a 19-kilometer (12-mile) inlet in the Northeast part of Prince William Sound. Valdez is accessible by road, sea, and air, primarily through the Richardson Highway, the Port of Valdez, and the Valdez Airport, respectively. Valdez maintains a year-round population of approximately 4,500 residents, with another 800 to 1,000 seasonal residents.

The Port of Valdez is also the terminus of the 1,287-kilometer (800-mile) long Trans-Alaska oil pipeline. Supertankers regularly navigate the Port of Valdez to transport more than 1.5 million barrels per day. The port serves other industries such as commercial fishing, seafood processing plants, and tourist traffic including several cruise ships per year.

Port Adak Potential SBX Mooring Area

Adak, Alaska

Figure 2.3.1-16

Source: Census 2000 Tiger/Line Data, 2002 (modified).
The City Dock would not accommodate the SBX and currently cannot accommodate cruise ships. The City of Valdez is working to upgrade the City Dock to accommodate cruise ships. The North Pacific Fuel Dock, next to the City Dock, is deep enough to accommodate the SBX at high tide. Pier-side operations could be carried out for the SBX at the Container Dock where depths exceed 15.2 meters (50 feet). Valdez does not maintain the pier capacity to commit Container Dock pier-space year round for the SBX, which would yield to cruise ships during the tourist season of May through September. However, there are mooring locations near the container dock and across the Port of Valdez near the Alaska Pipeline terminus. Figure 2.3.1-17 shows a general location of the Port of Valdez.

The Container Dock has approximately 8.5 hectares (21 acres) of staging area. This area is one potential location for constructing warehouse and administration space. The “Old Town” area of Valdez, destroyed in the 1964 earthquake, is another possible location for constructing warehouse and administration space.

### 2.3.1.11 Mobile Telemetry and C-Band Radar

As described in section 2.1.5.3, Mobile Telemetry Systems and mobile C-band radar would be required to support the flight testing as a part of the proposed GMD action. Target telemetry requirements include an up-range, mid-range, and down-range telemetry system to support launches. A relatively level area or improved road would be required to site the systems. Intended operations would be to pull the telemetry and radar equipment into a prepared area and utilize a commercial power drop. Generators would provide a backup source of power. Uninterrupted Power Supplies are contained in each unit as an emergency backup if power is lost during a test flight.

### 2.3.1.12 AN/SPY-1 Radar

See section 2.1.5.2.2 for a description of the AN/SPY-1 radar system. The Aegis ship would be positioned at various locations in the Pacific to provide missile tracking support during a GMD test.

### 2.3.1.13 Sea Launch Target

See section 2.1.2.2 for a description of the Sea Launch Target. The MLP would be positioned at various locations in the Pacific to provide target missiles during a GMD test.

### 2.3.1.14 Air Launch Target

See section 2.1.2.2 for a description of the Air Launch Target. The Air Launch Target plane would be positioned at various locations in the Pacific to provide target missiles during a GMD test.

### 2.3.1.15 Cobra Judy

See section 2.1.5.2.2 for a description of the Cobra Judy system. The Cobra Judy ship would be positioned at various locations in the Pacific to provide missile tracking support during a GMD test.

GMD ETR Final EIS

Source: Census 2000 Tiger/Line Data, 2002 (modified).
2.3.1.16 Components of the Validation of Operational Concept That Would Also Support GMD ETR Testing

As discussed in section 1.5, the operationally realistic testing of the GMD element directed by MDA is part of the BMDS Test Bed and consists of ground testing to validate the GMD operational concept, and robust flight testing to validate the GMD components. The GMD ETR has several activities and facilities in common with the Validation of Operational Concept testing, including:

- Cobra Dane Radar at Eareckson Air Station, Alaska
- Early Warning Radar at Beale AFB, California
- GFC Nodes at Peterson AFB, Colorado; Schriever AFB, Colorado; Cheyenne Mountain Complex, Colorado; Beale AFB, California; Eareckson Air Station, Alaska; Fort Greely, Alaska; and Boeing facilities in California and Alabama

2.3.2 ALTERNATIVE 2

Alternative 2 would be similar to Alternative 1 with the exception that GBI launches would be from Vandenberg AFB and RTS instead of KLC and RTS. The GBI launch would require construction of an IDT and modifications of existing support facilities at Vandenberg AFB. The existing TPS-X radar at Vandenberg AFB would be utilized. The other components described in Alternative 1 would remain the same.

2.3.2.1 Vandenberg Air Force Base

Under Alternative 2, Vandenberg AFB would continue to be a launch site for GMD target missiles and would support single and dual GBI launches. The following activities would occur at Vandenberg AFB:

- Single and dual launch of target missiles
- Single and dual launch of GBI missiles
- Construction and operation of a fixed or relocatable IDT
- Use of the existing TPS-X radar
- Use of existing range instrumentation

2.3.2.1.1 Target Launch

The facilities required to support target missile launches are described in section 2.3.1.5.

2.3.2.1.2 Ground-Based Interceptor Launch

The following facilities located on Vandenberg AFB may be required for the GBI tests: two silos (to be chosen among silos LF-2, LF-3, LF-10, LF-21, LF-23, and LF-24); Buildings 975, 976, 1032, 1768, 1777, 1801, 1819, 1871, 1900, 1959, 1970, 1978, 6510, 6819, 7000, and 8500, as shown on figure 2.3.2-1 and listed in table 2.3.2-1. Many of these facilities have been used to support GBI booster verification tests and as such would require only minor interior modifications to support continued GMD testing.

Note: If LF-03 is used as a GBI silo, then an additional silo would need to be identified to support a dual target launch. At such time as dual launch requirements are defined, additional environmental planning would be carried out as required.

Buildings 1032, 1819, and 1900 may be used for missile assembly and interceptor integration and checkout before launch, and storage of testing and checkout equipment for the GBI missile. They may require facility modifications such as hazardous material detection, alarm, and ventilation to accommodate the EKV processing operations. Building 1900 could be used for missile transporter storage; Buildings 1777, 1801, and 1959 could be used for maintenance and storage. Building 6819 is an existing explosive storage facility that would be used for missile storage. Building 1970 would be used as a storage facility for supporting equipment.

Storage facilities for EKV tanks with small quantities (7.5 liters [2 gallons] or less each) of fuel and oxidizer would be Building 975 for the oxidizer and Building 976 for the fuel.

Buildings 1768 and 1801 could be used as the Launch Control Center for the GBI tests. Modifications inside the buildings would be required.

Buildings 1801, 1900, 1959, 6510, and 8500 would be used for administrative space. Most facilities would require minor modifications. However, Building 1801 would require fairly extensive interior modifications, and the facility has the potential to encounter lead-based paint and asbestos.
LF-21 and LF-23 are currently used for GMD Booster Verification testing. LF-02 is an active silo currently used by the Peacekeeper missile program. LF-03 is an active silo currently used as an MDA target missile silo. LF-10 is an active silo currently used by the Minuteman III missile program. LF-24 is an inactive Minuteman II silo.

Site preparations and modifications were made to LF-21 in order to utilize it for Booster Verification test flights. These modifications were analyzed in the Booster Verification Tests EA (1999). Refurbishments have also been made to LF-23 in order for it to be utilized for GBI launches. These refurbishments were made for the Alternate Boost Vehicle test program and have been previously analyzed under the Alternate Boost Vehicle Verification Tests EA (2002).

Some level of modifications and site preparation could be required at each of the remaining LFs included in the Proposed Action. The proposed launch sites would each include the launch silo, equipment located above ground and within existing below-ground locations, the existing silo access roadways, site utility distribution, and any auxiliary mechanical support equipment. Site preparation could include modifying the existing silo(s) to receive a new prefabricated launch station that would accommodate the installation of the GBI. A “headworks” consisting of a foundation and silo top block would provide an interface for insertion and removal of the GBI. An operational launch silo closure mechanism would be installed at each LF.

All construction staging areas would be located on paved or previously disturbed graded areas. The GMD program would perform sampling and abatement for lead-based paint, asbestos, and polychlorinated biphenyls (PCBs) as required before modification, using Vandenberg AFB-approved procedures. If any of the modifications require the removal of these hazardous wastes, they would be properly disposed of in accordance with work plans developed by GMD personnel and approved by Vandenberg AFB 30th Civil Engineering Squadron/Environmental Management Flight (30 CES/CEV).

**In-Flight Interceptor Communication System Data Terminal**

As described in section 2.1.3, the IDT at Vandenberg AFB could be a fixed land-based unit, a relocatable unit, or a sea-based unit. A fixed IDT would be contained in a building that is approximately 30.7 meters by 11.6 meters (101 feet by 38 feet) and would have a 5.5-meter (18-foot) diameter radome mounted on one end of the building (figure 2.1.3-1). The radome, which covers the antenna, would be inflatable. An external aboveground fuel tank would be located near the building. The mission backup power generator would be located adjacent to the IDT. This generator would be rated at 300 kW and would be housed in a 3.4- by 1.5-meter (11- by 5-foot) wide enclosure. An additional modular facility (or facilities) would be temporarily installed within approximately 30 meters (100 feet) of the IDT. This modular facility would be used to provide spare components and repair parts storage and workspace for technicians. There could be an environmentally protected entrance between the IDT and the modular facility. The modular facility would require communications and utility hookups including local commercial power. Interior water tanks and chemical toilets, inside the modular facility, would be frequently serviced and negate the need for water utility pipes and a septic tank system. The estimated size for these facilities would be approximately 186 to 465 square meters (2,000 to 5,000 square feet). Up to 10 technicians would observe, operate, test, and maintain this facility.
The IDT site would disturb approximately 5.9 hectares (14.6 acres), and include a fenced area of approximately 3.2 hectares (8.0 acres). One IDT site would be selected from the alternative IDT locations shown on figure 2.3.2-1 and listed in table 2.3.2-2. Either a fixed or relocatable IDT could be located at the selected site on Vandenberg AFB. Once the IDT site is selected, the layout would be finalized with installation personnel including 30 CES/CEV. Construction of the IDT would require approximately 35 personnel for a period of 6 months.

</tr>
</tbody>
</table>

The relocatable IDT would essentially be a modular design with a radome similar to the fixed IDT. Operational requirements would be similar to those of the fixed IDT, including a stable foundation, electricity, communications, utilities, security, lighting, and monitoring systems.

Operations and security requirements would be as described in section 2.1.3.

Communications Cable

For communication among the components at Vandenberg AFB, the ETR would maximize use of available communications assets, to include cable. If communication cable is not available, new cable would be installed in new conduits, which would be placed in routes designed to avoid environmental impacts and approved by 30 CES/CEV. Trenching for the new communications cable/conduit would have a maximum depth of 0.91 meter (3 feet). Slant/directional drilling is also being proposed as a means of minimizing impacts to the environment if required. Also, the new communications cable/conduit would be buried along existing roads, if possible.

If previously undocumented cultural resource items are discovered during excavation, grading, or other ground-disturbing activities, work would immediately cease. In addition, work would be temporarily suspended within 30 meters (100 feet) of the discovered item until it has been properly evaluated and secured. Any discovery of previously unidentified cultural resources would be reported to the Vandenberg Base Historic Preservation Officer.
Reuse of LF-2, LF-3, or LF-10 would require consultation with the California State Historic Preservation Officer and potential mitigation. Alteration or reuse of any other National Register-eligible Cold War-era facilities would be included in the required consultation.

2.3.2.1.3 Launch Complex Security

When interceptor testing occurs, it would be on a periodic basis. It is assumed that testing would be on a campaign basis, and the security for these tests would be on a similar basis. It is estimated that the potential security impacts would occur for several weeks for each campaign.

GBI security force personnel would support each campaign. A Security Response Force Outpost would be established in the vicinity of the launch facilities and would be coordinated with Vandenberg security personnel. The installation of additional facility-mounted exterior lighting and chain link security fencing could be required.

Additional physical protection features may be constructed or placed to protect GMD assets. These may include, but are not limited to, fences, security lighting, bollards, tapered concrete barriers or similar devices, ditching and/or earth mounds, patrol roads, and observation tower(s).

Estimates are for several security vehicles to be used. During the operational day, vehicles would be on patrol. At night, additional vehicles would be used as needed. Normal patrols would be confined to existing roads. There would be occasions when these vehicles could be expected to go off-road.

2.3.2.2 Kodiak Launch Complex

The proposed actions at KLC under Alternative 2 are identical to those described under Alternative 1 for Target missiles. No GBI launches or silo, IDT, or COMSATCOM construction would occur at KLC under Alternative 2. Tables 2.3.2-3 through 2.3.2-5 list existing and proposed facilities for Alternative 2 at KLC.

2.3.2.3 Midway

The proposed actions at Midway under Alternative 2 are identical to those described under Alternative 1. See section 2.3.1.2 for a description of construction and operations of IDT at Midway. Although Midway was an alternative site in the Draft EIS, MDA has determined that it is no longer a reasonable alternative and will not be a proposed site for ETR activities. The IDT on-board the SBX would perform the function that had been planned for Midway. The discussion of Midway has been retained in the Final EIS, however, in order to preserve the work that has already been performed.

2.3.2.4 Reagan Test Site

The proposed actions at RTS under Alternative 2 are identical to those described under Alternative 1. See section 2.3.1.3 for a description of dual GBI launches and the SBX PSB at RTS.
2.3.2.5 Pacific Missile Range Facility

The proposed actions at PMRF under Alternative 2 are identical to those described under Alternative 1. See section 2.3.1.4 for a description of single target launches and potential operating areas for TPS-X at PMRF.

2.3.2.6 Pearl Harbor, Hawaii
See section 2.3.1.6 for a description of the SBX PSB at Pearl Harbor, Hawaii.

2.3.2.7 Naval Base Ventura County Port Hueneme, California
See section 2.3.1.7 for a description of the SBX PSB at NBVC Port Hueneme, California.

2.3.2.8 Naval Station Everett, Washington
See section 2.3.1.8 for a description of the SBX PSB at Naval Station Everett, Washington.

2.3.2.9 Adak, Alaska
See section 2.3.1.9 for a description of the SBX PSB at Adak, Alaska.

2.3.2.10 Valdez, Alaska
See section 2.3.1.10 for a description of the SBX PSB at Valdez, Alaska.

2.3.2.11 Mobile Telemetry and C-Band Radar
See section 2.3.1.11 for a description of mobile telemetry and C-band radar usage to support GMD ETR tests. The mobile telemetry and C-band radar would be positioned at various locations to provide missile tracking support during a GMD test.

2.3.2.12 AN/SPY-1 Radar
See section 2.1.5.2.2 for a description of the AN/SPY-1 radar system. The Aegis ship would be positioned at various locations in the Pacific to provide missile tracking support during a GMD test.

2.3.2.13 Sea Launch Target
See section 2.1.2.2 for a description of the Sea Launch Target. The MLP would be positioned at various locations in the Pacific to provide target missiles during a GMD test.
2.3.2.14 Air Launch
See section 2.1.2.2 for a description of the Air Launch Target. The Air Launch Target plane would be positioned at various locations in the Pacific to provide target missiles during a GMD test.

2.3.2.15 Cobra Judy
See section 2.1.5.2.2 for a description of the Cobra Judy system. The Cobra Judy ship would be positioned at various locations in the Pacific to provide missile tracking support during a GMD test.

2.3.2.16 Components of the Validation of Operational Concept that Would Also Support GMD ETR Testing
The proposed actions addressed in the Validation of Operational Concept EA under Alternative 2 are identical to those described under Alternative 1. See section 2.3.1.16 for a list of facilities and activities that are a part of ETR flight testing that have been analyzed in the Validation of Operational Concept EA.

2.3.3 ALTERNATIVE 3—COMBINATION OF ALTERNATIVES 1 AND 2
Alternative 3 would include activities proposed for Alternatives 1 and 2. This would include GBI launches from KLC, RTS, and Vandenberg AFB, and construction of the required support facilities for dual launches of GBI and target missiles at each location. At KLC Alternative 3 is the same as Alternative 1.

2.4 ALTERNATIVES CONSIDERED BUT NOT CARRIED FORWARD
As a logical progression leading to the construction of the GMD ETR components, and as an integral part of the NEPA process, a siting study, including the identification of and evaluation of alternative candidate locations, was conducted. Components of the GMD ETR element were evaluated in accordance with the methodology presented in the Ballistic Missile Defense Organization Directive No. 6051, Comprehensive Siting Analysis Process. The process consists of several phases: identification of the performance region, Area Narrowing, and Location Evaluation. Exclusionary and evaluative criteria are defined and applied to discriminate among potential candidate locations and sites, and to measure the relative suitability of each to support component operation and sustainment.

The following sections summarize the results of the GMD ETR Siting Study regarding locations that were considered for GMD ETR components but were not carried forward for analysis.

2.4.1 GBI LAUNCH LOCATION ALTERNATIVES
Johnson Atoll, PMRF, and Wake Island were candidate GBI locations that were considered but not carried forward. Johnson Atoll was eliminated because it does not have a functionally similar mission due to the recent transfer of the atoll back to the USFWS. PMRF was not carried forward as a GBI launch location due to its location in line with the other two primary launch locations, Vandenberg AFB and RTS. Due to the flight geometries, a GBI launch site at PMRF would not meet the ETR test objectives. Wake Island was evaluated as a subset of RTS. Due to the proximity of Wake Island and Meck Island in the overall ETR, only one of the sites
could be used. Wake Island was not selected because the facilities at Meck Island are far superior to the facilities at Wake Island.

2.4.2 TARGET LAUNCH LOCATION ALTERNATIVES

Johnson Atoll and Wake Island are the only candidate target locations that were not carried forward. As discussed for the GBI, Johnson was eliminated because it does not have a functionally similar mission due to the recent transfer of the atoll back to the USFWS. Wake Island does not provide additional trajectory options when compared to RTS and lacks the instrumentation available at RTS.

2.4.3 IDT LOCATION ALTERNATIVES

2.4.3.1 Remote Land-Based IDT

The remote IDT Performance Region is located in the middle of the Pacific Ocean. Kure and Midway Atoll (Eastern, Sand, and Spit Islands) were evaluated as candidate locations for the Land-based IDT within the Mid-Pacific performance region. Kure Atoll, Eastern Island, and Spit Island were not carried forward due to insufficient acreage and lack of available infrastructure.

Although Midway was an alternative site in the Draft EIS, MDA has determined that it is no longer a reasonable alternative and will not be a proposed site for ETR activities. The IDT onboard the SBX would perform the function that had been planned for Midway. The discussion of Midway has been retained in the Final EIS, however, in order to preserve the work that has already been performed.

2.4.4 SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE ALTERNATIVES

The SBX has three candidate performance regions (figure 2.1.4-3). Using the three Performance regions, potential locations for a PSB were identified from one of three geographic areas located within a 2,667-kilometer (1,440-nautical-mile) distance of each performance region. The three areas include southwest Alaska, the U.S. West Coast, and the south/middle Pacific. A minimum of two potential locations in each of the geographic areas were evaluated as PSB Alternatives.

In the southwest Alaska area, Port of Anchorage and Port of Seward did not meet the Mission Compatibility criteria that a PSB location must be capable of supporting storage and transfer of supplies for large-scale commercial shipping activities. The harbor must currently maintain infrastructure to berth and support an offshore supply vessel requiring at least a 24.4-meter (80-foot) pier. Additionally, the location cannot have current or planned activities that would conflict with GMD requirements either at pierside or offshore mooring location.

In the U.S. West Coast area, Naval Magazine Indian Island, Detachment Concord, Naval Submarine Base San Diego, and Naval Weapons Station San Diego, California; and Naval Submarine Base Bangor and Puget Sound Naval Shipyard, Washington, did not meet the Mission Compatibility criteria.
In the south/middle Pacific area, Johnson Atoll, Kaneohe Bay, Hawaii, and Wake Island did not meet the Mission Compatibility criteria. Midway Atoll did not meet the Ownership criteria that the PSB facility shall be located on U.S. DoD land not dedicated toward special-use purposes, or historical sites, etc., or set aside for purposes which are incompatible with the proposed GMD usage.

Based on the application of evaluative criteria, a preliminary rank-order list of 11 sites was developed.

The decision was made to carry forward the top ranked sites, but not more than two sites per area. Sites carried forward in the ETR EIS include:

- Alaska: Port Adak, Alaska and Port of Valdez, Alaska
- U.S. West Coast: Naval Station Everett, Washington and NBVC Port Hueneme, California
- South/Middle Pacific: Naval Station Pearl Harbor, Hawaii and RTS, Kwajalein Atoll

Locations not carried forward for further analysis included Naval Station San Diego and Naval Station North Island, California; Dutch Harbor and U.S. Coast Guard Station Kodiak, Alaska; and Naval Station Bremerton, Washington.

A supplemental SBX siting study is underway to support the initial defensive operations capability mentioned in section 1.2. Because the SBX operations at the PSB in support of initial defensive operations would be identical to those in support of the ETR, the supplemental siting study will start with the six PSB locations identified for the ETR. The application of additional evaluative criteria related to initial defensive operations will be applied to determine the final rank order of the six candidate PSBs. This ranking is likely to be different than the preliminary rank order of the 11 sites.

2.4.5 MOBILE TELEMETRY AND MOBILE C-BAND RADAR LOCATION ALTERNATIVES

Locations evaluated as potential sites for mobile telemetry and mobile C-band radar but not carried forward for further analysis included Soldotna, Kenai, King Cove, Sand Point, Seldovia, Cold Bay, Dillingham, Sitka, Juneau, and Chignik, Alaska. The lack of sufficient parcel size, supportability, commercial power, and line of sight requirements made these sites unsuitable for the placement of mobile telemetry and mobile C-band radar.
3.0 AFFECTED ENVIRONMENT

This chapter describes the environmental characteristics that may be affected by the Proposed and Alternative Actions. The information provided serves as a baseline from which to identify and evaluate environmental changes resulting from construction and operation required for the GMD ETR program. To provide a baseline point of reference for understanding any potential impacts, the affected environment is briefly described; any components of greater concern are described in greater detail.

Available reference materials, including EAs, EISs, environmental baselines, monitoring reports, and base master plans, were reviewed. To fill data gaps (questions that could not be answered from the literature) and to verify and update available information, installation and facility personnel; federal, state, and local regulatory agencies; and private individuals were contacted.

Environmental Resources
The affected environment is discussed in terms of 14 resource areas: air quality, airspace, biological resources, cultural resources, geology and soils, hazardous materials and hazardous waste, health and safety, land use, noise, socioeconomics, transportation, utilities, visual and aesthetic resources, and water resources. In addition, subsistence resources are discussed for potential Alaska sites. Each resource area is discussed at each location as applicable. Environmental justice is discussed separately in section 3.12.

Existing Related Environmental Documentation
The FAA prepared an EA in 1996 for the construction and operation of KLC, which supported the licensing of the complex for commercial operations (Federal Aviation Administration, 1996). The U.S. Air Force prepared an EA in 1997 that proposed launching two sub-orbital test vehicles (the atmospheric interceptor technology [ait] program) on a southeasterly course from KLC (U.S. Department of the Air Force, 1997a). The U.S. Air Force also prepared an EA in 2001 that proposed launching one Quick Reaction Launch Vehicle (QRLV) per year beginning in 2001 and ending in 2008 (U.S. Department of the Air Force, 2001). The U.S. Army Space and Missile Defense Command prepared an EA in 2001 that proposed launching the Strategic Target System from KLC and PMRF (U.S. Army Space and Missile Defense Command, 2001b). These documents discuss the existing affected environment on Kodiak Island in detail and are incorporated into this document by reference.

Several NEPA documents have been prepared for activities on Midway, including the EA for the Proposed Refuge Logistics and Operations Support and Public Use Program at Midway Atoll National Wildlife Refuge, 1996, and the 1997 Public Use Plan for Midway Atoll National Wildlife Refuge. These documents discuss the affected environment in detail and are incorporated by reference.

The existing environment at RTS was described in the Final Supplemental EIS for Proposed Actions at USAKA (U.S. Army Space and Strategic Defense Command, 1993a). This document discusses the affected environment in detail and is incorporated by reference.
The existing environment at PMRF was described in the *Pacific Missile Range Facility Enhanced Capability Environmental Impact Statement* (Pacific Missile Range Facility, Barking Sands, 1998) and the *North Pacific Targets Program Environmental Assessment* (U.S. Army Space and Missile Defense Command, 2001b). These documents discuss the affected environment in detail and are incorporated by reference.

The documents mentioned above, and other related environmental documents, are summarized in appendix A. The following sections summarize applicable data from the documents mentioned above. Information from other sources of data is specifically referenced.

### 3.1 KODIAK LAUNCH COMPLEX

The existing environment at KLC was described in the *Environmental Assessment of the Kodiak Launch Complex* (Federal Aviation Administration, 1996), the *Final Environmental Assessment for U.S. Air Force Quick Reaction Launch Vehicle Program* (U.S. Department of the Air Force, 2001), the *Final Environmental Assessment for the North Pacific Targets Program* (U.S. Army Space and Missile Defense Command, 2001b), and the *Environmental Assessment for the U.S. Air Force Atmospheric Interceptor Technology Program* (U.S. Department of the Air Force, 1997a). For the most part, those descriptions are still accurate and are not repeated in this document. Rather, for resources that may be affected by ETR activities at KLC, the pertinent resource discussions are summarized and any differences in existing environmental conditions, including new facilities or infrastructure, are noted. The more detailed discussion in the Final EAs are incorporated by reference and will be made available for review by those who wish for more information concerning the existing environment at KLC.

#### 3.1.1 AIR QUALITY—KODIAK LAUNCH COMPLEX

Appendix B includes a definition of air quality and the main regulations and laws that govern its protection.

##### 3.1.1.1 Region of Influence

Identifying the region of influence (ROI) for air quality assessment requires knowledge of the pollutant types, source emission rates and release parameters, the proximity relationships of project emission sources to other emission sources, and local and regional meteorological conditions. For inert pollutants (all pollutants other than ozone and its precursors), the ROI is generally limited to an area extending no more than a few kilometers downwind from the source. The prevailing wind direction is from the northwest. The ROI for ozone may extend much further.
downwind than the ROI for inert pollutants; however, as the project area has no heavy industry and very few automobiles, tropospheric ozone and its precursors are not of concern.

The ROI for project operational activities is a circular area with a 5-kilometer (3.1-mile) radius centered on the site of activity. This ROI distance was chosen due to previous analysis in the KLC EA (Federal Aviation Administration, 1996). In that EA the highest concentration of launch emissions was predicted on an uninhabited mountain 5 kilometers (3.1 miles) from the existing launch site. Most activities would be centered at KLC. However, one or two remote telemetry sites would be chosen in Alaska from the sites listed in section 2.1.5.3.

3.1.1.2 Affected Environment

Climate

The climate of Kodiak is characterized as maritime, including short, cool summers and long mild winters. Winter weather tends to last from November to March, with an average daily temperature of -1°C (30°F). Average wind speeds reach 19 kilometers (12 miles) per hour during these winter months. The months of September and October are considered fall, with temperatures between 4°C and 10°C (40°F and 50°F) and winds averaging 16 kilometers (10 miles) per hour. The summer months, June to August, are characterized by average daily highs of 15.6°C (60°F). April and May are regarded as spring months, in which the average monthly temperatures are from 1°C to about 4°C (34°F to about 40°F), and the windspeeds are approximately 19 kilometers (12 miles) per hour.

Surface winds along the coast are much stronger and more persistent than at inland areas. While winds tend to be from the northwest at about 19 kilometers (12 miles) per hour, high winds occur throughout the year. Peak gusts range from 56 kilometers (35 miles) per hour in June to 134 kilometers (83 miles) per hour in December. Typically 1 day of heavy fog occurs per month, with visibility of 0.4 kilometer (0.25 mile) or less. During July, fog averages 3 days per month. (Federal Aviation Administration, 1996) The largest monthly snowfall occurs during December and January, with the maximum snowfalls ranging from 100 to 110 centimeters (40 to 45 inches) per month.

Regional Air Quality

Kodiak Island is classified as a Class II attainment area. It is part of a larger area that is in attainment with the National Ambient Air Quality Standards (NAAQS) (Alaska Legislature, 2002). The island’s climatology includes periods of high winds and overcast skies, which make the island’s atmosphere optimal for dispersion of air pollutants. The atmosphere is classified as neutral (D stability) for this dispersion capability. (Federal Aviation Administration, 1996)

Existing Emission Sources

Wind-blown volcanic dust is the primary air contaminant on the island. Human activities in the vicinity of KLC that would affect background air quality are ranching, occasional vehicular traffic, the occasional operation of two standby generators at the U.S. Coast Guard Loran-C Station, and the periodic use of KLC for vehicle launches.

Backup power at KLC is provided by diesel-driven standby generators located at the Launch Control Center, Payload Processing Facility, and Integration and Processing Facility. All
generators at the complex have block heaters and are contained in heated enclosures. Gas particulate air emissions from launch operations at KLC include the rocket-motor exhaust plume emitted during launch and diesel generator emission. Table 3.1.1-1 lists the estimated emissions generated by the four standby generators at KLC. KLC currently maintains a Preapproved Limit Permit for these generators.

Table 3.1.1-1: Existing Generator Emissions at KLC

Table 3.1.1-2 lists the estimated concentration of the principal pollutants in the exhaust products from the Athena-2 (formally known as the Lockheed Martin Launch Vehicle) as presented in the KLC EA (Federal Aviation Administration, 1996). The Athena-2 was selected because it represents the largest class of solid rocket booster that can be flown from KLC.

</tbody>
</table>

Source: Federal Aviation Administration, 1996.

$^{(1)}$ Castor 120 motor
μg/m$^3$ = micrograms per cubic meter  ppm = parts per million

Under worst-case meteorological conditions, which are estimated to occur 2 percent of the time, the maximum downwind concentrations of hydrogen chloride and aluminum oxide would occur at an uninhabited 610-meter (2,000-foot) high mountain peak and would be within the applicable air quality standards. (Federal Aviation Administration, 1996)

U.S. Air Force Standards are appropriate since the ceiling limit set by the Occupational Safety and Health Administration (OSHA) is for stationary sources (such as inside an industrial plant). However, launches are classified as mobile sources and their emissions are temporary. The standard is based on measured and estimated launch emission exposure concentrations and durations in the event of normal and catastrophic launches. (National Research Council, Commission of Life Sciences, Board of Environmental Studies and Toxicology, Committee on Toxicology, Subcommittee on Rocket-Emission Toxicants, 1998)
3.1.2 AIRSPACE—KODIAK LAUNCH COMPLEX

Airspace, or that space which lies above a nation and comes under its jurisdiction, is generally viewed as being unlimited. However, it is a finite resource that can be defined vertically and horizontally, as well as temporally, when describing its use for aviation purposes. The time dimension is a very important factor in airspace management and air traffic control.

Under Public Law (PL) 85-725, *Federal Aviation Act of 1958*, the FAA is charged with the safe and efficient use of our nation’s airspace and has established certain criteria and limits to its use. The method used to provide this service is the National Airspace System. This system is “…a common network of U.S. airspace; air navigation facilities, equipment and services, airports or landing areas; aeronautical charts, information and services; rules, regulations and procedures, technical information and manpower and material.” Appendix B includes a detailed description of airspace.

3.1.2.1 Region of Influence

The ROI for airspace at KLC includes commercial air corridors, and the airspace over and surrounding KLC (figure 3.1.2-1).

3.1.2.2 Affected Environment

Controlled and Uncontrolled Airspace

The closest controlled airspace is approximately 40 kilometers (25 miles) northeast of KLC at the Kodiak Airport. Class C and Class D airspace is in effect at Kodiak Airport. Airspace above KLC up to flight level (FL) 180 is uncontrolled class G airspace. Airspace above FL 180 is controlled airspace. The Anchorage Air Route Traffic Control Center (ARTCC) and the Kodiak Air Traffic Control Tower regulate air traffic in the vicinity of KLC.

Special Use Airspace

KLC coordinates launches with airspace users through the existing airspace coordination protocol among KLC, commercial aircraft carriers, and military aircraft. Launches from KLC do not affect U.S. Air Force training exercises.

En Route Airways and Jet Routes

Commercial air corridors enter and exit Kodiak Airport to and from the west, north, and south. Routes include G2 (J604), G10, R341, B27 (J123), V506, V439, V438, and V357. These corridors are north of the Narrow Cape area, more than 24 kilometers (15 miles) from the launch area to the edge of the V506 Corridor. Although generally north of KLC, orient-bound aircraft use flexible tracks to transition to the North Pacific route system. These routes are generated based on the prevailing jetstream and their position relative to KLC may vary. These routes are not depicted on charts. Current coordination procedures minimize any potential impacts to aircraft on these routes. (Goward, 2002)

**Airports/Airfields**
Kodiak Airport is the airport closest to KLC. It is located approximately 40 kilometers (25 miles) northeast of the launch site. It is a state operated regional airport that routinely handles daily passenger and cargo jet service and has accommodated C-141 and C-5 military aircraft.

**3.1.3 BIOLOGICAL RESOURCES—KODIAK LAUNCH COMPLEX**
Appendix B includes a definition of biological resources and the main regulations and laws that govern their protection. For this analysis, scientific names are only provided the first time that threatened and endangered species are mentioned in the text, unless required for clarification.

**3.1.3.1 Region of Influence**
The ROI includes areas that may potentially be affected by construction and operation activities. The ROI includes KLC and surrounding areas within a 9.7-kilometer (6-mile) radius of launch pad 1, as determined during original agency consultation in 1996, such as Ugak Island and Narrow Cape, which may be affected by noise, toxic spills, and debris.

**3.1.3.2 Affected Environment**
**Vegetation**
The predominant vegetation types covering KLC include hairgrass-mixed forb (broad leaved herbs) and open willow-hairgrass-mixed forb meadow, shrublands, wetlands, and intermittent stands of spruce (figure 3.1.3-1) (Alaska Aerospace Development Corporation, 1995b). Some of the most common plants are hairgrass, meadow fescue, alder, willow, and Sitka spruce. The vegetation community structure of the Narrow Cape region has been affected by grazing from farmed cattle, bison, and horses (Alaska Aerospace Development Corporation, 1995b).

*Threatened and Endangered Plant Species*
No federally proposed or listed candidate, threatened, or endangered plant species have been observed within the boundaries of KLC.

**Wildlife**
The KLC site provides habitat for about 143 species of birds. Typical birds found in the area include loons, grebes, harlequin ducks, kingfishers, chickadees, juncos, sparrows, and terns.

Seabird colonies and nesting areas in the vicinity of KLC are shown in figure 3.1.3-2. The seabird colony closest to the KLC site, believed to be an Arctic and Aleutian tern colony, is approximately 3 to 5 kilometers (2 to 3 miles) north of the launch pad. This colony was not active during a 1994 survey, and has not been active since (Cuccarese, 2002). Ugak Pass is attractive to marine birds year-round due to its shallow waters and abundant fish and invertebrates.

The bald eagle, which is protected by the Bald and Golden Eagle Protection Act, is common throughout the year on Kodiak Island and is often seen in the Narrow Cape area. Aerial surveys were conducted in the spring of 1999, 2000, and 2001 to document bald eagle nesting activities at KLC. One active nest was observed at Narrow Cape and one at Lone Point, 8 kilometers (5 miles) north of Narrow Cape. Nine bald eagles were observed in 2000, with the same two nests appearing active. Twelve bald eagles were observed in 2002, with indications of possibly three active nests (Narrow Cape and Lone Point, and Bird Point, which is approximately 3 kilometers [2 miles] north of Narrow Cape). (Alaska Aerospace Development Corporation, 2002b)

Little brown bat, tundra vole, red fox, brown bear, short-tailed weasel, and river otter are common terrestrial mammals found at KLC. Snowshoe hare, red squirrel, muskrat, beaver, Sitka black-tailed deer, buffalo, and mountain goat are examples of species introduced to Kodiak Island.

Horses, cattle, and bison graze nearby under lease to a local ranch. A 2-meter (7-foot) chain link fence surrounds each of the structures at KLC to prevent animals from wandering onto the launch complex.

The fence and nearby steep topography keep grazing animals away from the launch stool. The nearest game trail passes approximately 76 meters (250 feet) south of the launch stool location (U.S. Department of the Air Force, 2001).

The harbor seal is a year-round resident of the area. Several haulout and general use areas occur near KLC, the closest of which is Ugak Island, approximately 5 kilometers (3 miles) southeast. The northern fur seal occurs offshore of the KLC site from January through April. The sea otter is found along most of Kodiak Island’s coast in all months of the year. A number of cetacean species, including Dall’s and harbor porpoise, Pacific white-sided and Risso’s dolphins, and killer whales, are found year-round in the water surrounding Kodiak Island. The migratory path of the recently delisted gray whale includes the eastern nearshore edge of Kodiak Island. The greatest number of gray whales in this area occurs during April, May, November, and December. (Alaska Aerospace Development Corporation, 1995b)

**Essential Fish Habitat**

Approximately 12 percent of the KLC site is occupied by open water including small streams, two freshwater lakes, and a series of lagoons. Two of the streams have been incorporated into the Alaska Department of Fish and Game’s anadromous stream catalog since coho salmon juveniles were detected there (Alaska Aerospace Development Corporation, 1995b). The waters south of Kodiak Island, including the Narrow Cape vicinity, are essential habitat for commercially important fish species year-round. Habitat Areas of Particular Concern include all streams, lakes, and other freshwater areas used by salmon and other anadromous fish. The closest major salmon stream to KLC is the Pasagshak River, which is approximately 10 kilometers (6 miles) to the northwest. Alternate barge landing sites 1, 2, and 3 are close to small order anadromous fish streams, which support pink salmon and are listed in the Alaska Department of Fish and Game’s “Anadromous Fish Stream Catalogue” (McCrea, 2003). The most common marine fish in nearshore and offshore water around Kodiak Island are flounder, sole, pollock, skate, cods, and halibut. Other common marine organisms include crabs, scallops, octopus, shrimp, and clams.
Threatened and Endangered Wildlife Species

No federally proposed or listed candidate, threatened, or endangered species are located within the boundaries of KLC. However, several species occur in the ROI, including marine waters in the area (table 3.1.3-1). The Steller sea lion (*Eumetopias jubatus*) population near Kodiak Island was included in the population classified as endangered in 1997. Ugak Island, approximately 5 kilometers (3 miles) southeast of KLC, contains the closest sea lion haulout. No Steller sea lion rookeries have been identified in the ROI (Smith, 2001). Although seven whale species are found in the waters near Kodiak Island, only the delisted gray whale and the endangered humpback whale (*Megaptera novaeangliae*) use the nearshore waters of Kodiak Island within the ROI (Federal Aviation Administration, 1996). Humpback whales are generally found in the nearshore areas of Kodiak Island in the summer. They have been occasionally observed in the Narrow Cape and Ugak Island area. Figure 3.1.3-2 depicts the locations of seabird colonies and pinniped haulout areas in the vicinity of KLC.

Source: U.S. Fish and Wildlife Service, 2000

-- = Not Listed  E = Endangered  SSC = State Species of Special Concern  T = Threatened

Most of the world’s Steller’s eiders (*Polysticta stelleri*) winter along the Alaskan Peninsula, an area that includes Kodiak Island, and through the Aleutian Islands. Most of the world’s Steller’s eiders nest in northeastern Siberia with a small portion (less than 5 percent) nesting in Alaska (State of Alaska Online, 2002c). The USFWS has classified this Alaska nesting population as threatened. The Steller’s eiders occur in the Kodiak Island area primarily during the winter months. Rafts of Steller’s eiders were primarily observed offshore of North and South Lagoons and offshore of Pasagshak Bay during surveys conducted in 1997 and 1998 (Alaska Aerospace Development Corporation, 1998).

The federally and state endangered short-tailed albatross (*Phoebastria albatrus*) could occur in the ROI primarily during the summer months (U.S. Fish and Wildlife Service, 2000). The short-tailed albatross is a very large seabird with narrow 2-meter-long (7-foot-long) wings. Adults also spend the summer non-breeding season at sea, feeding on squid, fish, or other organisms. Most summer sightings are in the Aleutian Islands, Bering Sea, and Gulf of Alaska. (State of Alaska Online, 2002b) The world population, which is increasing, is estimated to be 1,200 (U.S. Fish and Wildlife Service, Alaska Region, 2001).
Environmentally Sensitive Habitat

Wetlands
Wetlands in Alaska are defined by the U.S. Army Corps of Engineers as “those areas that are inundated or saturated by surface or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions. Wetlands generally include swamps, marshes, bogs, and similar areas.” The U.S. Army Corps of Engineers Alaska District and the U.S. Environmental Protection Agency (EPA) regulate wetlands through the Clean Water Act Section 404 Permitting Program. Wetlands cover approximately 29 percent of the KLC site, as shown in figure 3.1.3-1. Palustrine, emergent, persistent, seasonally flooded and palustrine scrub/shrub, broad-leaved deciduous, saturated wetlands are located within the area proposed for the new GBI launch site.

Critical Habitat
In surveys around Kodiak and southern Afognak Islands, Steller's eiders were reported to be present, and hundreds to low thousands are counted during the Christmas Bird Count in Kodiak. Consistent and extensive use of the Kodiak area by the Steller's eider has been observed. Although critical habitat has not been designated in the Kodiak Archipelago, the area still contains important habitat for Steller’s eiders and protection afforded by the Endangered Species Act still applies.

Critical habitat for the Steller sea lion includes a special aquatic foraging area in the Shelikof Strait area consisting in part of an area between the Alaskan Peninsula and Kodiak Island (50 CFR 226.202, Critical Habitat for Steller Sea Lions). This area is along the western side of Kodiak Island and outside the ROI.

3.1.4 CULTURAL RESOURCES—KODIAK LAUNCH COMPLEX
Appendix B includes a description of cultural resources and the laws and regulations pertaining to them.

3.1.4.1 Region of Influence
The term ROI is synonymous with the area of potential effect as defined under cultural resources regulations (36 CFR 800.16[d], Protection of Historic Properties, Program Alternatives). In general, the ROI for cultural resources encompasses areas requiring ground disturbance (e.g., areas of new facility or utility construction) and all buildings or structures requiring modification, renovation, demolition, or abandonment. At KLC this includes the locations described in section 2.3.1.1 and shown on figures 2.3.1-2, 2.3.1-3, and 2.3.1-4.

3.1.4.2 Affected Environment
Prehistoric and Historic Archaeological Resources
In 1994, the Alaska State Office of History and Archaeology performed an archaeological survey in and around the KLC site. The study focused primarily on areas near the following facilities: the existing Integration and Processing Facility, the existing Launch Pad 1, the proposed Missile Assembly Building, the proposed GBI silos, the existing Payload Process Facility, the proposed
Oxidizer Storage, and the existing Launch Control Center (figures 2.3.1-2 and 2.3.1-4). There was no evidence of cultural resources recorded during this survey. However, there are two archaeological sites and a World War II bunker complex within approximately 1.6 kilometers (1 mile) of KLC. (Federal Aviation Administration, 1996)

**Historic Buildings and Structures**

The first recorded contact with the Kodiak natives occurred in 1763 by the Russian Stephen Glotov and in 1792 by the Russian fur trapper Alexander Baranov. The Russians continued to explore the area primarily to search for sea otter. As the Russians began to settle the area, Kodiak became the first capital of Russian Alaska. As the area was settled, the sea otter population fell to near extinction and the Kodiak natives’ culture had significantly declined. By 1867, Alaska had become a U.S. territory. In 1882, the opening of a fish cannery produced the development of commercial fishing in the area. In 1940, the Town of Kodiak was established.

Kodiak Island was used extensively by the U.S. Army and the U.S. Navy during World War II, and the population of the island rose to more than 25,000. The U.S. Navy constructed a submarine base and an air station while the U.S. Army constructed an outpost near the Buskin River. (Alaska Department of Community and Economic Development, Division of Community and Business Development, 2002)

**Native Populations/Traditional Resources**

The primary native population of Kodiak is a group of Alaska Native people known as the Alutiiqs. Some archaeologists believe that the Alutiiq people have occupied the Kodiak region for at least 7,000 years. Several distinct cultural traditions have been identified in the Kodiak Island region, including the Ocean Bay (ca. 4500–1400 BC), the Kachemak (ca. 1400 BC–1200 AD), the Koniaq (ca. 1200–1784 AD), and the Chugash, who were present when the first Europeans arrived.

The Koniaqs and Chugash lived in permanent sod houses in the winter and set up temporary fish camps in the summer. They hunted whales, seals, sea lions, and sea otters with harpoons and clubs. Salmon was also a major dietary staple of all the Alutiiqs.

When Russian hunters began to occupy the region to benefit from sea otter furs, they used Native labor to assist them. The Alutiiq men were forced to hunt at sea while the women and children worked on the shore. Before the Russians had established a colony on Kodiak Island, there were approximately 8,000 Alutiiq. By the time the Russians left, the Alutiiq population had fallen to around 2,000 (kodiakisland.net, 1999).

Previous archaeological surveys have indicated that cultural resources are not present in upland areas occupied by KLC. However, records have indicated the presence of cultural resources near 2 of the proposed barge landing sites described in section 2.3.1 and shown in figure 2.3.1-1. Koniaq house pits and refuse have been identified near Barge Landing Site 1 – Narrow Cape Vicinity and Koniaq house pits and shell midden have been found near Site 3 – Pasagshak Bay Area (Bittner, 2003).
Paleontological Resources
Paleontological resources on the upland areas of KLC are generally found in the Narrow Cape formation which is located below the surface soils. These resources include shallow-water marine invertebrates of Oligocene and Miocene age. (Alaska Department of Natural Resources, 2003)

3.1.5 GEOLOGY AND SOILS—KODIAK LAUNCH COMPLEX
Geology and soils are those earth resources that may be adversely affected by the proposed GMD ETR test program. This resource is described in terms of landforms, geology, and soil conditions as they could contribute to erosion, depletion of mineral or energy resources, and soil contamination resulting from proposed construction and launch activities. The potential for geologic hazards is also described as relative to each site’s geologic setting. A geologic hazard is a naturally occurring or man-induced geologic condition that presents a risk or a potential danger to life and property. Such hazards could include phenomena such as landslides, flooding, ground subsidence, volcanic activity, faulting, earthquakes, and tsunamis.

3.1.5.1 Region of Influence
The ROI is anticipated to be the locations described in section 2.3.1.1 and shown on figures 2.3.1-1 through 2.3.1-4, and soil areas within each Launch Hazard Area that might be subject to contamination from launch exhaust emissions and/or potential contamination from unburned fuel in the event of a terminated launch.

3.1.5.2 Affected Environment
This section draws heavily from the Subsurface Investigation and Geotechnical Recommendations Report for KLC that was prepared by R&M Consultants, Inc. (Alaska Aerospace Development Corporation, 1995b) and on a series of seismic hazard evaluation studies conducted for the U.S. Coast Guard Loran Station by Carver Geologic, William Lettis and Associates, and International Civil Engineering Consultants, Inc. (U.S. Coast Guard Civil Engineering Unit, 2001; 2002; 2003).

Physiography
KLC is located in northeastern Kodiak Island on a low-lying coastal area that forms a prominent headland at the southeast corner of the site called Narrow Cape. KLC is bounded from the southwest to the east by the Gulf of Alaska. The Marin mountain range fringes the northern boundary of KLC and achieves local elevations of greater than 640 meters (2,100 feet) less than 1.6 kilometers (1 mile) to the northwest (U.S. Geological Survey, 1952). The surface topography of KLC is characterized by a series of gently undulating northeast-southwest trending ridges approximately 43 to 110 meters (140 to 350 feet) in elevation. The ridge tops are broad, and the ground surface on the ridge tops is relatively level. The flanks of the ridges typically have moderate to steep slopes, and there is approximately 15 to 46 meters (50 to 150 feet) of topographic relief between ridge tops and adjacent valleys. The ridges terminate on the southwest end in a near-vertical bluff of exposed silty fine sandstone to a siltstone that meets the beach above the high tide line. The northeast ends of the ridges slope gradually down to the beach and lagoons located along the eastern shore of Narrow Cape (Alaska Aerospace Development Corporation, 1995b).
Geology

Narrow Cape is underlain by folded, faulted, thickly bedded to massive course clastic sediments of the Sitkalidak and Narrow Cape formations (U.S. Coast Guard Civil Engineering Unit, 2002). Lithologies include siltstone, fine and medium lithic sandstone, pebbly sandstone and conglomerate. The sediments are thickly bedded to massive and in many places contain large concretions up to 2 meters (7 feet) in diameter (U.S. Coast Guard Civil Engineering Unit, 2002). Weathered bedrock has a field textural classification of sand with traces of some silt, grading to highly weathered bedrock with a textural classification of sand with trace silt and gravel, with particles of sandstone core stones making up the gravel fraction. The thickness of the completely weathered bedrock is about 0.3 to 2 meters (1 to 7 feet), with the thicker weathered zones occurring in topographically low areas (Alaska Aerospace Development Corporation, 1995b).

Soils

The upland soils that compose the bulk of KLC are described by the U.S. Department of Agriculture (1960) as being of the Kodiak soils series. These soils developed from the weathered bedrock (sandstone) and were covered by volcanic ash from a 1912 eruption about 140 kilometers (90 miles) west of Kodiak Island. A surface litter 10 centimeters (4 inches) thick of partly decayed vegetation has accumulated on the volcanic ash. These upland soils are well-drained but are usually moist due to frequent rains (Alaska Aerospace Development Corporation 1995). Erosion of the upland soils located on slopes of less than 7 percent is not considered to be a problem. As the slopes of upland areas increase toward the adjacent valleys (i.e., greater than 7 percent), the erosion hazard may become serious (U.S. Department of Agriculture, 1960).

The soils in the valleys near KLC are a combination of Saltery peat and Ugak silt loam soils (Alaska Aerospace Development Corporation, 1995b). The Saltery soils have developed where the water table is always at or near the surface and consist of a deep layer of peat 76 centimeters (30 inches) or more in depth overlain by about a 30-centimeter (12-inch) layer of ash and a new 8- to 10-centimeter (3- to 4-inch) layer of peat at the surface. The Ugak soils associated with these valley soils have only a 2.5-centimeter (1-inch) layer of peaty material beneath the layer of volcanic ash. These soils occur in poorly drained areas and are very strongly acidic to strongly acidic (U.S. Department of Agriculture, 1960).

Geologic Hazards

Kodiak Island is located on the upper plate of the Aleutian subduction zone, the convergent boundary between the Pacific and North American plates. The Aleutian megathrust (the fault between the two plates) is one of the earth’s largest active faults and has produced three of the world’s six largest magnitude earthquakes of the last 100 years, including the great (moment magnitude [Mw] 9.2) 1964 “Good Friday” or Great Alaska earthquake. (U.S. Coast Guard Civil Engineering Unit, 2001) In addition to the megathrust, the subduction zone also includes several other active fault systems. Numerous faults with high levels of historical activity are contained at depth and within the subducting Pacific plate. In the Kodiak Island region since 1999 these “slab” earthquakes include several in the magnitude range of 6.5 to 7+. A second system of active faults is present in the upper plate (North American plate) of the subduction zone. These faults comprise a wide fold and thrust belt that extends along the eastern side of Kodiak Island and continues to the northeast into the Prince William Sound region. These faults also produce frequent earthquakes. During the 1964 “Good Friday” earthquake, two of the fold and thrust belt faults produced large surface displacements on Montague Island in Prince
William Sound and others probably also ruptured the sea floor offshore of Kodiak, contributing to the generation of the destructive tsunami. (U.S. Coast Guard Civil Engineering Unit, 2001)

In addition to the Aleutian megathrust (and the subducting Pacific plate), there are several significant fault sources in the Kodiak region that could generate large earthquakes. The U.S. Coast Guard Civil Engineering Unit (2002) identified four active faults or zones of faults capable of generating large magnitude earthquakes at Narrow Cape. These include the Albatross Bank fault zone, the Kodiak Shelf fault zone, the Narrow Cape fault and the Kodiak Island fault (figure 3.1.5-1). Each of these faults includes several individual faults or fault segments that are seismogenic; however, the characteristics of the earthquake sources are poorly known (U.S. Coast Guard Civil Engineering Unit, 2001). In support of probabilistic and deterministic seismic hazard evaluations for the U.S. Coast Guard Loran Station (U.S. Coast Guard Civil Engineering Unit, 2002), a table characterizing the seismic sources for Narrow Cape was prepared, including maximum earthquake magnitude and recurrence interval estimates (table 3.1.5-1). Based on the source models selected for the probabilistic seismic hazard analysis, the potential maximum magnitude ($M_{max}$) events (judged to generate the largest ground motions at the site) were a $M_{7.5-8.0}$ on the Narrow Cape fault zone and $M_{8.5}$ on the Kodiak Interplate Subduction Segment. (U.S. Coast Guard Civil Engineering Unit, 2003)

The Narrow Cape fault also poses a surface rupture potential at KLC. The U.S. Geological Survey mapped the Narrow Cape fault off-shore for a proposed off-shore oil lease. The U.S. Geological Survey concluded that the fault was active and provisional maps projected the main trace and several subsidiary branches on-shore at Narrow Cape within a 6-kilometer (3.7-mile) zone. The main trace is about 2 kilometers (1.2 miles) west of the Loran site and one of the subsidiary branches was demonstrated to traverse the Loran site. Paleoseismic investigations concluded that the scarps were tectonic in origin and that there may have been three to four episodes of Holocene displacement on each of three trenched branch faults of the Narrow Cape fault. Topographic scarps, offset drainages, and other geomorphic evidence of youthful deformation to the marine terrace were also mapped at Narrow Cape (U.S. Coast Guard Civil Engineering Unit, 2002). Detailed fault studies have not been performed for the entire KLC site.

Great earthquakes generated in the Gulf of Alaska often generate tsunamis (seismic sea waves). In southern Alaska, 37 significant historical earthquakes of $M_{7.0}$ or greater have generated evidence of 14 tsunamis (U.S. Coast Guard Civil Engineering Unit, 2002). The tsunami resulting from the 1964 earthquake was reported by a Narrow Cape rancher to have inundated low-lying areas along the eastern shore (Alaska Aerospace Development Corporation, 1995b). KLC facilities are located above the 30-meter (100-foot) elevation above sea level recommended by the City of Kodiak for safe refuge from flooding due to tsunamis (Alaska Aerospace Development Corporation, 1995b).

There are no active volcanoes on Kodiak Island. As discussed in the soils section, KLC can be subject to ash falls from active volcanoes in the Aleutian chain. Over 40 volcanoes are active in the Aleutian arc, generating 256 eruptions over recorded history (Ballistic Missile Defense Organization, 2000). Such eruptions could cause nuisance ash falls at the site, create a significant hazard to various types of equipment and electronics, or possibly create atmospheric conditions that would temporarily delay air transport or flight tests.

Source: U.S. Coast Guard Civil Engineering Unit, 2002

Mw = Moment magnitude
NA = Not Available
A landslide approximately 430 meters (1,400 feet) long is located on slopes of 15 to 35 percent along a valley just north of Ranch Road, where it intersects Pasagshak Point Road just north of KLC. The landslide feature itself may actually extend to within the project site boundaries and was apparently caused by rotational slumping of the poorly indurated sandstone (Alaska Aerospace Development Corporation, 1995b).

3.1.6 HAZARDOUS MATERIALS AND HAZARDOUS WASTE—KODIAK LAUNCH COMPLEX

Appendix B includes a discussion of hazardous materials and hazardous waste resource regulations.

3.1.6.1 Region of Influence

The ROI for potential impacts related to hazardous materials/wastes includes areas of KLC to be used for new construction, pre-launch site preparation, launch, and post-launch activities, and in areas where hazardous materials are stored and handled.

3.1.6.2 Affected Environment

Hazardous Materials Management

Hazardous material use, storage, and disposal are managed in adherence with the KLC Safety Policy, the KLC Emergency Response Plan, KLC Contamination Control Procedures, AADC’s HazCom Program, the Kodiak Area Emergency Operation Plan, and applicable state and federal environmental laws, in such a way as to minimize impacts to the environment.

An AADC point of contact is notified before the arrival of any hazardous materials at KLC and outlines the guidelines for proper handling, storage and disposal. All contractors must provide hazardous materials information (Material Safety Data Sheet [MSDS]), label and warning signs, and a plan indicating material handling/storage procedures, spill/release prevention measures, and emergency response protocol, including cleanup and disposal procedures and first aid/medical treatment procedures. (Alaska Aerospace Development Corporation, 2001)

Table 3.1.6-1 lists hazardous materials that may be used at KLC.

Hazardous Waste Management

AADC is authorized to operate KLC as a Small Quantity Generator according to the Alaska Hazardous Waste Management Regulations (18 Alaska Administrative Code [AAC] 62). With this designation, KLC can produce no more than 998 kilograms (2,220 pounds) of hazardous waste per month, which normally amounts to just under five drums of liquid hazardous waste. The types of hazardous and nonhazardous wastes generated during routine operations at KLC are indicated in table 3.1.6-2.

3 Payload Processing Facility
4 Launch Area

These wastes are handled, transported, and disposed of in accordance with AADC’s HazCom Program, KLC Safety Policy, KLC Contamination Control Procedures, and applicable state and federal environmental laws. Pollution prevention, waste minimization and recycling procedures are indicated in the KLC Spill Prevention Control and Countermeasures (SPCC), Emergency Response Plan and Contamination Control Procedures.

There are no Installation Restoration Program (IRP) issues associated with KLC, since it is not a DoD installation. No NPL site is listed for Kodiak Island in the EPA’s Comprehensive Environmental Response, Compensation, and Liability Information System database.

KLC has aboveground storage tanks (ASTs) for diesel fuel storage. Diesel is used to fuel generators for backup electrical power with electrical power being used for heating, ventilation, and air conditioning. KLC primary power is from Kodiak Electric Association. Petroleum, oil and lubricant (POL) storage is in accordance with federal (EPA) requirements at 40 CFR 112, and State of Alaska requirements at 18 AAC 75. KLC does not utilize underground storage tanks (USTs).

Because KLC was recently constructed, asbestos or lead-based paint is not present. Likewise, polychlorinated biphenyls (PCBs) should not be present in equipment or machinery.

Fuels are handled and stored in adherence to KLC Safety Policy, KLC Emergency Response Plan, and KLC Contamination Control Procedures. A description of the GBI solid rocket fuel and the EKV propellant system is in section 2.1.1. The propellant consists of a hypergolic fuel (monomethyl hydrazine) and oxidizer (mixed oxides of nitrogen). Monomethyl hydrazine is toxic and extremely reactive. Descriptions of candidate target missiles are in section 2.1.2. These missiles are representative of existing missile types launched from KLC.
3.1.7 HEALTH AND SAFETY—KODIAK LAUNCH COMPLEX

Health and safety includes consideration of any activities, occurrences, or operations that have the potential to affect the well-being, safety, or health of workers or members of the general public. Appendix B includes a discussion of health and safety resource regulations. Appendix C includes a detailed discussion of flight test safety.

3.1.7.1 Region of Influence

The ROI for potential impacts to the health and safety of workers includes the immediate work areas of KLC, including new construction areas; those areas associated with missile storage, assembly, and transfer; and the launch sites and areas associated with post-launch activities. If required, debris recovery and emergency operations could also potentially impact worker health and safety.

The ROI for potential impacts to public health and safety includes KLC, as well as off-range areas that may be affected by GMD ETR Program activities involving preflight transport of missile components, missile launch, and missile flight. A launch failure could potentially involve an explosion, missile debris, release of toxic materials into the air or water, high noise levels, and/or fire.

The public population of concern for the Proposed Action consists of people living in the vicinity of KLC, including occupants of Bear Paw Ranch and Burton (Kodiak) Ranch, U.S. Coast Guard personnel who periodically work at the Loran-C Coast Guard Station at Narrow Cape, members of the public who utilize the KLC area for recreation, and residents of eastern Kodiak Island, including the City of Kodiak and the U.S. Coast Guard Station (U.S. Department of the Air Force, 1997a). In general the area surrounding KLC is sparsely populated. The City of Kodiak (approximately 6,334 people according to the 2000 Census) and the U.S. Coast Guard Station, located approximately 48 to 64 kilometers (30 to 40 miles) from KLC, are the only sizable population centers on the island. Additional smaller population centers are located southwest of KLC and include Old Harbor (237) and Akhiok (80). There are also several dozen cabins located along the southeast coast of Kodiak Island that are occupied on a seasonal basis. The Range Safety program will assure that potential impacts will be well within the debris limit corridor and away from these populated areas.

3.1.7.2 Affected Environment

Range Safety

The KLC Safety Policy mandates the establishment of launch safety levels that meet or exceed those of the Range Commanders Council (RCC) Common Risk Criteria for National Test Ranges and Standard 321-02, AFR 127-1, FAA Notice of Proposed Rulemaking (NPRM). In accordance with the KLC Safety Policy, the criteria per year of Range operations for public casualty is limited to 1 in 1 million, and the casualty criteria for personnel involved in the launch is limited to 1 in 300,000.

Standard range safety procedures at KLC are conducted in accordance with RCC 321-02, AFR 127-1, FAA NPRM, etc. These procedures provide for ground safety, flight safety, range clearance and surveillance, sea-surface area clearance and surveillance, and commercial air
traffic control. They include published NOTMARs and NOTAMs, as well as coordination with the U.S. Coast Guard and FAA.

The AADC range organization assures that all aspects of safety are covered, including transport of missile components (i.e., solid propellant boosters), and handling of the booster and EKV (pre-loaded fuel and oxidizer tanks) once they arrive at KLC, operations at the launch site, flight safety, and RF interference. The KLC range organization is responsible for assuring that the test missiles, under any flight condition, will not endanger any life or property. The launch vehicle operator and/or payload operator submits a Ground Safety Plan to AADC for review and approval before launch operations.

During launch preparation, ground safety at KLC is the responsibility of AADC. Hazardous operations will be performed in compliance with mission-specific operating procedures that will provide the requirements and direction for the activities at KLC, including explosives handling safety, hazardous operations control, explosives storage, launch pad operations and launch. Safe operating procedures are followed in accordance with DoD Standard 6055.9.

A hazard potential is present during pre-launch transport, pre-launch processing, and launch of missiles due to the significant amounts of propellant contained in the boosters. The exposure to launch mishaps is greatest within the early portions of the flight after launch. Measures are currently in place to limit the number of personnel involved in the launch operations and to ensure that hazardous operations are performed by highly skilled personnel. Regulations and practices that have been established to minimize or eliminate potential health and safety risks to the general public include, but are not limited to, OSHA and DOT regulations and U.S. Air Force procedures for transporting hazardous materials, DoD procedures for handling explosives, and the DoD Range Safety program for the processing and launch of missiles (U.S. Department of the Air Force, 1997a).

Using standard explosive safety rules, AADC will determine areas that will be evacuated for each launch to assure that the public is not exposed to unacceptable levels of risk, that physical security and safety measures can be enforced, and that adverse environmental effects are minimized. The size of the evacuation area is based upon the potential for variability of the impact due to influences of local weather conditions, and small variances in the missile guidance and engineering systems.

To ensure public safety during launch days, KLC security personnel would close Pasagshak Point Road at the site boundary and ensure that no unauthorized personnel enter the Ground Hazard Area. The safety zone is under constant surveillance during the day of launch and during any hazardous operations. If the safety zone is compromised, the launch is delayed until the area is confirmed clear. Pre-launch notifications to aviators and mariners are issued 24 hours before launches.

Each launch at KLC has an established flight termination line. These lines are established to minimize potential adverse impacts on populated areas. In addition, procedures call for various contingency plans to be in effect. These include, but are not limited to the following:

- **Mishap:** An Explosive Ordnance Disposal Plan will be in place, along with appropriate personnel and equipment.
- **Fire:** There will be a firefighting crew in place during launch countdown.
- **Injury:** An evacuation plan will be in place to transport injured persons to medical facilities.

Previous launches have had no effect related to either public health and safety or range safety issues.

**Regional Safety**

In compliance with Superfund Amendments and Reauthorization Act Title III, AADC/KLC has filed Tier II Community Right-to-Know reports with the State Emergency Response Commission, the Local (Kodiak–Kodiak Island Borough) Emergency Planning Committee, and the City of Kodiak Fire Department. (Nault, 2002) The Local Emergency Planning Committee is a committee appointed by the Alaska State Emergency Response Commission to perform local emergency planning and community right-to-know activities. The *Kodiak Area Emergency Operation Plan* (Kodiak Emergency Services Organization, 2000) is a four-volume plan, assembled in part by the Division of Emergency Services, Alaska Department of Military and Veterans Affairs, to direct preparation for, response to, mitigation of, and recovery from natural and man-caused disaster emergencies within the Kodiak Island Borough, including KLC. The Plan is activated when a disaster emergency significantly threatens human health, property, or the environment. The Chief of the Kodiak Area Fire and Rescue Department is the Kodiak Emergency Services Coordinator.

The City of Kodiak Fire and Rescue Department has three firefighters/emergency medical technicians under the supervision of a lieutenant and two chiefs on duty at all times. During emergencies, on-line firefighters are supported by 15 to 20 volunteer firefighters with various levels of emergency medical technician training. The Kodiak Fire Department does not provide general/routine firefighting service for AADC/KLC, but would respond to wildland fires at AADC/KLC by agreement with the Alaska Department of Natural Resources, Division of Forestry. The Kodiak Fire Department has three ambulances and provides ambulance service and emergency medical response at the advanced and basic life support levels for AADC/KLC. The Kodiak Fire Marshal provides fire code enforcement, fire cause investigation, and other fire prevention services for AADC/KLC and also works with the U.S. Coast Guard Marine Safety Detachment in the planning and oversight for missile component off loading. (Nault, 2002)

The City of Kodiak Fire and Police Departments provide as-needed support for closure and security of the KLC and Kodiak Island road system during missile transport and launch. Support for transportation of missile components, including closure and security of KLC and the Kodiak Island road system, is mostly provided by the U.S. Coast Guard and Alaska State Troopers.

The KLC has a fire truck and a 946-liter (250-gallon) pumper mounted on a 0.9-metric-ton (1-ton) truck to fight any brush fires that may occur during a launch. The KLC also has an ambulance to transport any injured patients. During missions, Emergency Medical Technicians are present at the KLC with the oversight of Northwest Medical. During launch day operations a doctor is in attendance at the KLC.
The closest hospital to the KLC is Providence Kodiak Island Medical Center. The Medical Center is an approximate 25-bed hospital providing emergency, surgical, maternity, general medicine, physical therapy, and diagnostic services for the Kodiak Island Borough, including KLC.

3.1.8 LAND USE—KODIAK LAUNCH COMPLEX

Appendix B includes a definition of land use and the main federal land management responsibilities that apply.

3.1.8.1 Region of Influence
The ROI for land use includes the Narrow Cape region of Kodiak Island within and adjacent to the boundaries of KLC that are potentially affected by the launch of target and GBI missiles and the construction, modification, and operation of support facilities associated with the Proposed Action.

3.1.8.2 Affected Environment

Land Use
Kodiak Island is situated in the northern Gulf of Alaska, just east of the Alaska Peninsula. It has an area of about 890,000 hectares (2.2 million acres), making it the second-largest island in the United States after the island of Hawaii. Its land use generally consists of KLC, Kodiak Harbor and airport, the City of Kodiak and neighboring U.S. Coast Guard Station, and the Kodiak National Wildlife Refuge. The remainder of the island is primarily undeveloped and utilized for an extensive number of recreational activities with small locales of residential and business uses. (U.S. Air Force, 2001)

Approximately 40 kilometers (25 miles) southwest of the City of Kodiak lies Narrow Cape, home to KLC. KLC is located within the Kodiak Island Borough on a 1,504 hectare (3,717 acre) coastal plateau leased and managed by the AADC from the Alaska Department of Natural Resources, Division of Land through an Interagency Land Management Agreement. Land management plans, expressed by the KLC Master Plan, are intended to improve the efficiency of land use by minimizing conflicts and protecting the human and natural environments (BRHP Architects Engineers, Inc., 2002). KLC consists of primary facilities and a number of support facilities which cover approximately 17 hectares (43 acres). Approximately 1 percent of KLC is considered disturbed, leaving the remainder in its natural state. In accordance with the Interagency Land Management Agreement, most undeveloped areas of KLC are made available for ranch animal and wildlife grazing. (Alaska Aerospace Development Corporation, 1995b)

Traditionally used for ranching and recreation, the Narrow Cape area is primarily underdeveloped and very sparsely populated (Kodiak Launch Complex, 1998). KLC is primarily surrounded by state-owned land, which serves as a buffer between the small amounts of privately-owned property. Only a small number of man-made structures exist within the vicinity of KLC that are not directly affiliated with KLC operations. A summer camp to the west of KLC consists of approximately 2.02 hectares (5 acres), and a ranch northeast of KLC consists of approximately 65 hectares (160 acres) adjacent to KLC’s boundary. Approximately 16 hectares (40 acres) of land within the boundaries of KLC are utilized by the U.S. Coast Guard’s 190-meter (625-foot) tall Loran-C navigation transmitter facilities (U.S. Air Force, 2001).
Recreation

Recreational opportunities in the Narrow Cape area are abundant and available year round. Activities include fishing, hunting, hiking, camping, boating, beachcombing, and wildlife and scenic viewing. Recreation activity peaks during the summer months. (Alaska Aerospace Development Corporation, 1995b) The Pasagshak State Recreation Area, located approximately 10 kilometers (6 miles) northwest of KLC, offers campsites, picnic areas, potable water, and latrines accessible for public use. Historic World War II jeep trails, the Narrow Cape Hiking Trail, and Burton Ranch Hiking Trail are in the vicinity of KLC, and are acknowledged by the Alaska Natural History Association. However, the trails are not regularly maintained (Kodiak Launch Complex, 1998). Other activities such as hunting bison and Sitka black-tailed deer and horseback riding are available at a nearby ranch for a fee (Alaska Aerospace Development Corporation, 1995b).

Fossil Beach and East Twin Lake are located on KLC and offer limited access for general beach activities. Beach combing, fossil hunting, and whale watching are the most significant activities available. Limited beach access and evacuations usually occur for a matter of hours. Unstable weather conditions, or any mechanical problems resulting in an abort launch or launch rescheduling, may prolong an evacuation or closure.

According to the 1999 Pasagshak/Narrow Cape Area plan, Fossil Beach/Narrow Cape and Pasagshak Point were the recreational areas most commonly identified for future State Park expansion. Although at this time no park expansion has been proposed, its existing recreational value is acknowledged. (Kodiak Island Borough Community Development Department, 1999)

Coastal Zone Management

The KLC is located in the “zone of direct influence” of the coastal environment (State of Alaska, Office of the Governor, 2001). All federal development projects in a coastal zone and all federal activities which could directly affect a coastal zone must be reviewed to determine their consistency with the local Coastal Zone Management Plan. The initial development of KLC, as examined in the Environmental Assessment of the Kodiak Launch Complex, was reviewed and received a positive determination on 18 January 1996 that the activities were consistent with the state and local standards and policies. Additional actions involving the development of KLC and the launch of missiles in support of the North Pacific Targets Program have also undergone Coastal Consistency Determinations, resulting in positive determinations on 25 September 2001 that the activities are consistent with the state and local standards and policies.

3.1.9 NOISE—KODIAK LAUNCH COMPLEX

Appendix B includes a definition of noise and the main regulations and laws that govern it.

3.1.9.1 Region of Influence

The ROI for noise analysis is the area surrounding KLC within which humans and/or wildlife may suffer annoyance or disturbance from launches and other noise sources at KLC.
3.1.9.2  Affected Environment

Based on the land use of the Narrow Cape area, the most common man-made noise is from occasional traffic on the road from the City of Kodiak to Narrow Cape, from nearby off-road recreational vehicles, intermittently, from standby generators at the nearby U.S. Coast Guard Loran Station, and occasional rocket launches.

Table 3.1.9-1 lists noise levels recorded at Ugak Island, which is a Steller sea lion haulout site and is located approximately 5.6 kilometers (3.5 miles) from the launch site, during four of the five previous rocket launches at KLC. The ait-1 took place November 1998, the ait-2 September 1999, the QRLV March 2001, the Athena-2 September 2001. The Strategic Target System vehicle launch took place in November 2001; however, noise levels could not be recorded due to adverse weather conditions. (Alaska Aerospace Development Corporation, 2002b)

1 Recorded at Ugak Island (5.6 kilometers [3.5 miles])
L_{max} = Maximum Sound Level

Due to the short duration of launches, an A-weighted scale is used and dBA (A-weighted decibel [dB]) measurements are employed to adequately characterize the operational noise.

Maximum Sound Level (L_{max}) is applied to compare noise levels because of its ability to cover the entire sound spectrum, especially sounds audible to humans.

Sensitive human receptors from activities at KLC are located at Kodiak Ranch (the nearest residence), a distance of 3 kilometers (2 miles); Church Camp (the nearest business), a distance of 5 kilometers (3 miles); and Pasagshak State Recreation Area (the nearest public facility), a distance of 10 kilometers (6 miles) (Federal Aviation Administration, 1996). Figure 3.1.9-1 shows a map of the nearest sensitive human receptors.

Wildlife receptors are located at the shoreline around Narrow Cape and Ugak Island at or near the water surface. Section 3.1.3, Biological Resources, describes wildlife found at KLC.
3.1.10 SOCIOECONOMICS—KODIAK LAUNCH COMPLEX

Appendix B includes a general definition of socioeconomics.

3.1.10.1 Region of Influence

The ROI for socioeconomics is defined as Kodiak Island Borough. The Proposed Action site is situated on Narrow Cape, a relatively remote area of Kodiak Island. The primary areas of analysis will concern both the communities situated adjacent to KLC and key population centers, specifically the City of Kodiak.

3.1.10.2 Affected Environment

The main population center is the City of Kodiak, at the northeastern tip of the island, about 402 kilometers (250 miles) south of Anchorage. Kodiak is a transportation hub for southwest Alaska, and home of the largest U.S. Coast Guard base in the country (Kodiak Chamber of Commerce, 2001). Other, smaller, population centers are situated along the roadway within the northeastern portion of the island. Aside from KLC, the remainder of the island is mostly uninhabited, with roughly two thirds of the western side of the island made up of the Kodiak National Wildlife Reserve (Alaska Aerospace Development Corporation, 1995a).

Population and Housing

In comparison to other Alaskan boroughs and unified municipalities, the Kodiak Island Borough ranks eighth in population. As of 2000, the population of the Kodiak Island Borough was 13,913 people (U.S. Census Bureau, 2001). The Borough has experienced an average annual growth in population of approximately 4 percent from 1980, when the population was 9,939 people. The rate of growth within the borough from 1990-2000 was 4.5 percent annually, much lower than that of the state, at 14.0 percent (U.S. Census Bureau, 2001).

The population of the island is concentrated in the City of Kodiak, where about half of the population resides, and in the smaller population centers of Port Lions, Ouzinkie, Old Harbor, Akhiok, Karluk, and Larsen Bay. As of 2000, the City of Kodiak, at 6,334 people (City of Kodiak and Kodiak Island Borough, 2001), was the seventh largest city in Alaska, in terms of population. The U.S. Coast Guard base also represents a significant proportion of the island’s population, with 1,840 people as of 2000. The closest population center to KLC is Cape Chiniak with a population of 50 people. The population of the borough has shown a high degree of transience given the seasonal nature of the fishing industry, changes in personnel at the U.S. Coast Guard station, and cyclical nature of construction projects (Alaska Aerospace Development Corporation, 1995a).

As of 2000, there were an estimated 5,159 housing units within Kodiak Island Borough (U.S. Census Bureau, 2001), including mobile homes and the U.S. Coast Guard Station housing. During this time, there were 2,255 housing units in the City of Kodiak. Another estimated 670 residential units are found in more remote settings of Kodiak Island (Kodiak Chamber of Commerce, 2003). As of 2002, it was reported that within the City of Kodiak there were five hotels and motels containing a total of approximately 200 rooms, and 30 bed-and-breakfast establishments typically with one or two rooms each. Narrow Cape Lodge, a temporary lodging facility located approximately 4.8 kilometers (3 miles) from KLC, had 56 rooms, and the Coast
Guard maintains a 46-room guest house primarily to support temporary housing needs of personnel moving to or from Kodiak (Ellis, 2002).

While data is not collected on monthly vacancy rates, the Kodiak Convention and Visitors Bureau estimated an annual average vacancy rate of 45 to 50 percent (Federal Aviation Administration, 1996) but given the nature of tourism on the island, much seasonal variance is to be expected. In addition the Bureau of the Census reported vacancy rates of rental housing of 7.7 percent and 8.9 percent for Kodiak Island Borough and City of Kodiak respectively.

Income and Employment

The U.S. Bureau of the Census reported in 2000 that Kodiak Island Borough showed a per capita income of $22,195 (U.S. Census Bureau, 2001), a figure only marginally lower than the statewide average of $22,660. Showing a similar distinction, the City of Kodiak showed a per capita income of $21,552, marginally lower than both the borough and statewide averages. Conversely, Kodiak Island Borough showed a median household income of $54,636 (U.S. Census Bureau, 2001), slightly higher than the statewide average of $51,571. Further, the City of Kodiak showed a median household income of $55,142, higher than both the borough and statewide averages. In 2000, the Alaska Department of Labor reported the annual average monthly wage for workers in the Kodiak Island Borough was $2,469, having marginally increased from $2,364 in 1999.

Employment levels on Kodiak fluctuate throughout the year predominantly due to the seasonal nature of the fishing industry (City of Kodiak and Kodiak Island Borough, 2001). Employment usually peaks during the months of July, August and September when fish harvesting is busiest, and declines in November and December as yearly fishing quotas are reached. Unlike fishing communities that have few fishing seasons and a transient cannery workforce, for the most part those employed in Kodiak’s canneries live within the borough year round and are unemployed between seasons.

For this reason, Kodiak is characterized by large swings in its monthly unemployment rate throughout the year, from as low as 3.4 percent to as high as 16.5 percent. The average annual unemployment rate for the Kodiak Island Borough in 2000 was 8.8 percent (City of Kodiak and Kodiak Island Borough, 2001), significantly higher than the statewide average of 6.6 percent.

Kodiak is the center of fishing activities for the Gulf of Alaska. Its fishery is among the most diverse in the state. Kodiak is consistently one of the top fishing ports in the United States both in terms of quantity and value. In 1998, Kodiak was the nation’s third highest port in seafood volume and value, with 162 million kilograms (358 million pounds) of seafood landed, at a value of $79.7 million (Kodiak Chamber of Commerce, 2001). As such, the seafood industry (including fish harvesting and seafood processing) continues to be the dominant industry on the island, in terms of employment, with nearly one-third of the total employment (table 3.1.10-1). Seafood processors are some of the largest private employers on the island (table 3.1.10-2). In addition to the fish harvesting and processing sectors, there are also several government and educational institutions that operate fisheries-related research facilities in Kodiak. There is also a large recreational fishery in freshwater streams and lakes on Kodiak (Alaskan Command, 1996).

Source: Kodiak Chamber of Commerce, 2002a.

The U.S. Coast Guard and other government entities are the next largest employment sector. Between the various Coast Guard operating and support commands, there are approximately 1,380 military and civilian personnel (government workers) (City of Kodiak and Kodiak Island Borough, 2001) and 1,600 military dependents. The Coast Guard contributes an estimated total annual payroll of $35 million. Retail and wholesale trade accounted for about 11.6 percent, and the service sector, 14.8 percent (table 3.1.10-1). The remaining 9 percent was made up of construction, transportation, communication, utilities, financial services, insurance, and real estate.
Tourism, like many other Kodiak industries, is based on Kodiak’s natural resources. Visitor spending in fiscal year 2001 was estimated at $19.6 million. As is true elsewhere in Alaska, Kodiak’s visitor industry is seasonal, with approximately 76 percent of all visitors arriving during the summer months.

The University of Alaska Anchorage conducted an evaluation of the economic impacts of the Air Force’s November 1998 launch and September 2001 launch of an Athena 1 missile from KLC (Alaska Aerospace Development Corporation, 2002b). The summary of their findings provides information on the economic benefits from a missile launch as follows:

- Brought $4.4 (Athena 1) and $1.3 (Air Force) million dollars of new money into the Alaska economy
- Increased the Kodiak payroll by approximately $1.3 million (Athena 1) and $450,000 (Air Force)
- Generated jobs in a wide range of industries from food service and hotels to business and health services

### 3.1.11 TRANSPORTATION—KODIAK LAUNCH COMPLEX

Appendix B includes a definition and general discussion of transportation.

#### 3.1.11.1 Region of Influence

The ROI for transportation resources addressed in this EIS includes the ground, ocean, and aviation transport systems within or immediately adjacent to KLC.

#### 3.1.11.2 Affected Environment

Kodiak Island maintains a highly capable industrial and government logistics infrastructure. Kodiak Island is home to the largest U.S. Coast Guard station in the world which currently supports C-130 aircraft and H-60 helicopters as well as a number of fully equipped oceangoing patrol vessels. Personnel and most types of equipment can be transported to Kodiak Island on daily flights offered by Alaska Airlines and ERA Aviation. Rocket motors and other heavy equipment are transported by aircraft, barge, or container ship. (Alaska Aerospace Development Corporation, 2001)

**Aviation Transportation**

The airport at Kodiak is shared with the U.S. Coast Guard and is located approximately 6.4 kilometers (4 miles) southwest of downtown Kodiak. It is served by Alaska Airlines (flying 737 jets) and its affiliated airline, ERA Aviation (flying Convair 580 and Dash 8 propeller aircraft), as well as Peninsula Airways (Alaska Department of Transportation and Public Facilities, 1998). All three are regularly scheduled commercial airlines with published flight schedules. The Kodiak Airport is fully instrumented and operates three runways (2,286 meters [7,500 feet], 1,981.2 meters [6,500 feet], and 1,676.4 meters [5,500 feet]), which can support C-141 and C-5A military cargo aircraft. The airport is approximately 64.4 kilometers (40 miles) north of KLC (Alaska Aerospace Development Corporation, 2001) by road. Kodiak is one of the largest airports in the region, moving over 78,000 passengers in 1996 (Alaska Department of
Transportation and Public Facilities, 1998). As there is no airfield on KLC, boosters to date have predominately been flown into the Kodiak Airport, although in one case, arrival was by barge (Cuccarese and Kelly, 2002). The Municipal Airport, also located in Kodiak, has an 878.7-meter (2,883-foot) paved runway (Kodiak Chamber of Commerce, 2002b).

Ocean Traffic
Kodiak Island offers a full range of dockage and marine services for commercial fishing, cargo, passenger, and recreational vessels. Kodiak was identified as one of only two communities in Alaska that is a Commercial Service Facility (Alaska Department of Transportation and Public Facilities, 1998). The facilities are owned by the City of Kodiak and maintained and operated by the city's Harbor Department. Two harbors provide protected moorings for 650 vessels up to 45.7 meters (150 feet) in length. Large vessels, including the state ferry, cruise ships, and cargo vessels are moored at three deepwater piers. Pier I is a 62-meter (204-foot) general use and ferry facility. Pier II is a 282-meter (925-foot) City Dock used for container and commercial work. Pier III is a 268-meter (880-foot) cargo terminal. Twenty-seven-metric-ton (30-ton) Gantry cranes are available and a 27-metric-ton (30-ton) Paceco container lift is available at Pier III (City of Kodiak, 2002).

Sealift capability includes three facilities: CSX Lines Terminal (Pier III); Lash Marine Terminal, which is privately owned; and the City Dock (Pier II). CSX Lines Terminal provides container and contract stevedore service for general commercial cargo. Lash Marine Terminal provides services to several freight carriers, freight forwarders, and consolidators. Tug and barge service is available to Kodiak Island from Seattle and Anchorage. The Lash Terminal, located south of the U.S. Coast Guard Station on the main road to KLC, is a roll-on, roll-off operation with 136-metric-ton (150-ton) lift capability provided by a mobile crane. The Lash Terminal is licensed for explosive and hazardous materials handling. Seaport Terminal Services operates the terminal and provides all necessary support services. The terminal has 366.8 meters (1,200 feet) of dock space as well as a warehouse. The City Dock is serviced by both containerized ocean shippers and barge carriers (Alaska Aerospace Development Corporation, 2001). Kodiak is one of the leading freight shippers in southwest Alaska with 696 commodity shipments in 1995 (Alaska Department of Transportation and Public Facilities, 1998).

Ferry service is provided to Kodiak Terminal as part of the Alaska Marine Highway System (AMHS) southwest and south central routes. Since 1988, Kodiak has been one of the top two ports-of-call in southwest Alaska in terms of ridership (5,541 boarding in 1996) (Alaska Department of Transportation and Public Facilities, 1998). Both passenger and vehicle services (including commercial and construction equipment vehicles) are available. In June 2002, the AMHS was officially designated as a National Scenic Byway. However, this designation has not altered policies and procedures for shipping, nor introduced any new restrictions (Reeves, 2002).

Road Traffic
From Kodiak, access to KLC is via Rezanof Drive West (also referred to as the Chiniak Highway) and Pasagshak Point Road. This road was previously paved for the first 9.7 kilometers (6 miles) outside of Kodiak, at which point it becomes a gravel surface; activities are currently underway which continue to extend the paved portion (Schoenthal, 2002). This road is narrow and, in some cases, steep. There are switchbacks and 11 bridge crossings before reaching KLC. All launch-related deliveries must be transported over this road, unless the
option is made to utilize barge transport. The Alaska Department of Transportation and Public Facilities has evaluated all of these bridges and made improvements to them to support rocket motors in transport to KLC (Alaska Aerospace Development Corporation, 2001). The average daily traffic (ADT) for Rezanof Drive just south of Kodiak airport was 2,081 in 2000 (Alaska Department of Transportation and Public Facilities, Division of Planning, 2000).

Roadways supporting the individual facilities within KLC are designed to accommodate tractor-trailer transport vehicles as well as passenger vehicles and light trucks. Road grades range from 1 percent to over 15 percent. Access roads within KLC are either improved or paved with asphalt. Access roads from the Launch Control Center to the Payload Processing Facility are 4.9 meters (16 feet) wide with 1-meter (3-foot) shoulders. Access roads from the Payload Processing Facility to the Transportation Center and Payload Processing Facility are 6.1 meters (20 feet) wide with 1.8-meter (6-foot) shoulders. Site roads at the Launch Control Center and Payload Processing Facility are 5.5 meters (18 feet) wide with 1-meter (3-foot) shoulders. Site roads at the Integration and Processing Facility and Launch Pad-1 are 7.6 meters (25 feet) wide with 1.8-meter (6-foot) shoulders. All these roads are paved asphalt.

Roadway design between the Payload Processing Facility, Integration and Processing Facility, and Launch Pad-1 presumes spacecraft are arriving at the Payload Processing Facility horizontally. Roadway design provides a minimum 45.7-meter (150-foot) inside turning radius for areas where transporters will travel (Alaska Aerospace Development Corporation, 2001).

AADC and the Alaska Department of Transportation and Public Facilities have conducted extensive studies of road and bridges and culvert crossing conditions and determined they are adequate for motor loads as heavy as a Castor 120™ (Alaska Aerospace Development Corporation, 2001). These findings have been confirmed through subsequent usage. For example, for the Athena-2 (Federal Aviation Administration, 1996), a Castor 120 motor was successfully barged onto the Lash Dock Terminal and then trucked over the road to KLC.

3.1.12 UTILITIES—KODIAK LAUNCH COMPLEX

Appendix B includes a definition and general discussion of utilities.

3.1.12.1 Region of Influence

The ROI for utilities is the area within or immediately adjacent to the KLC facility and the community in the vicinity of the KLC that serves the facility. The ROI also includes the area/region defined and served by the specific utility purveyors.

3.1.12.2 Affected Environment

Kodiak Island has approximately 14,000 residents, with roughly half living within the City of Kodiak. Kodiak Island maintains a highly capable industrial and governmental logistics infrastructure, and is home to the largest U.S. Coast Guard station in the world.

Energy

Electricity is provided by the Kodiak Electric Association, which has a capacity of 1,050 kW. A cooperative facility, Kodiak Electric Association operates and purchases power from the state-owned Terror Lake Hydroelectric Facility (Vacation Sites, Inc., 1999). Kodiak Electric
Association also operates a Coast Guard-owned plant, and owns three additional diesel-powered plants at Swampy Acres, Kodiak, and Port Lions. (Alaska Department of Community and Economic Development, Division of Community and Business Development, 2002)

A three-phase, 24.9/14.4-kilovolt (kV) overhead electric power line terminates approximately 640 meters (2,100 feet) north of the U.S. Coast Guard Loran Station. This line is a radial feed from a substation located 9.7 kilometers (6 miles) away. A single-phase line extends to serve the Launch Control Center and a three-phase line runs to each main building. The three-phase line to the Launch Control Center and Payload Processing Facility is underground in the Pasagshak Point Road shoulder. The line to the Launch Area is underground to a distance of 670 meters (2,200 feet) south-southeast of the Loran Station.

Each location has a step-down transformer providing 480 volts power for each facility. Each facility has a 277 Y/480-volt main switch-board for distribution to larger items of equipment. A dry-type step-down transformer that provides 120 Y/208-volt power for receptacles and other equipment is also located at each facility (Alaska Aerospace Development Corporation, 2001). The primary transformer capacity for each facility is 500 kVA at the Launch Control Center, 750 kVA at the Payload Processing Facility, 750 kVA at Launch Pad-1, and 750 kVA at the Integration and Processing Facility (Cooper, 2002).

Backup power is provided by diesel-driven standby generators located at the Launch Control Center (with a capacity of 350 kW, 400 horsepower), Payload Processing Facility (with a capacity of 500 kW), and the Launch Pad-1/Integration and Processing Facility (with a capacity of 600 kW) (Cooper, 2002). All generators at the complex have block heaters and are contained in heated enclosures. All generators start automatically upon loss of normal power source and provide backup power for all essential equipment within the facility. Maximum capacity of each generator is 72 hours for normal operations. Each generator has a 9,500-liter (2,500-gallon) storage tank available for No. 2 diesel fuel (Cooper, 2002). The Launch Pad is serviced by the generator for the Integration and Processing Facility. Limited uninterruptible power supply backup power is provided for critical equipment in areas where required for facilities use. Users may bring their own uninterruptible power supply systems for specific equipment, racks, and test sets as appropriate (Alaska Aerospace Development Corporation, 2001).

Peak power demand for KLC to date has been 825 kW (Cooper, 2002).

**Water**

Though the City of Kodiak is the supplier of water services in and around the city, outlying residents rely on private wells, as does KLC, which maintains water supply wells on KLC property.

Three identical packaged domestic water supply systems, each housed in a heated building, provide pressurized domestic water service for the Launch Control Center (26.5 liters [7 gallons] per minute of output and system design capacity of 9,464 liters [2,500 gallons] per day), Payload Processing Facility (11.4 liters [3 gallons] per minute of output and system design capacity of 1,136 liters [300 gallons] per day), and Integration and Processing Facility (well abandoned, system design capacity of 2,461 liters [650 gallons] per day). The Integration and Processing Facility uses a water storage tank with a 624,600-liter (165,000-gallon) capacity. (Cooper, 2002)
Each package consists of a submersible well pump, an automatic chlorinator, a 757-liter (200-gallon) storage tank, and a booster pump to maintain operating pressure. A dirt and rust filter is provided at the Launch Control Center and Integration and Processing Facility. A manual isolation valve bypass is used to fill the fire protection water storage tank from the Payload Processing Facility well.

Water system demand for the Launch Control Center, Payload Processing Facility, and Integration and Processing Facility during a mission has been estimated at 50 percent of the available design capacity of 13,060 liters (3,450 gallons) per day. During non-mission status the demand has been estimated at 5 percent of this available capacity. (Cooper, 2002)

Wastewater
On KLC, sanitary sewerage treatment is provided by elevated septic systems and elevated absorption fields. Individual systems are provided for the Launch Control Center, Payload Processing Facility, and Integration and Processing Facility. The system at the Launch Control Center is an 11,356-liter (3,000-gallon) septic tank with a 306-cubic meter (10,800-cubic foot) mound-type absorption bed, with a total system design capacity of 9,464 liters (2,500 gallons) per day. The system at the Payload Processing Facility is a 4,732-liter (1,250-gallon) septic tank with 82-cubic foot (2,904-cubic foot) mound-type absorption bed, with a total system design capacity of 1,136 liters (300 gallons) per day. The system at the Integration and Processing Facility is a 4,732-liter (1,250-gallon) septic tank with 106.2-cubic meter (3,750-cubic foot) mound-type absorption bed, with a total system design capacity of 2,461 liters (650 gallons) per day. (Cooper, 2002)

Wastewater treatment capacity for the Launch Control Center, Payload Processing Facility, and Integration and Processing Facility during mission status has been estimated at 50 percent demand of available supply, and during non-mission status has been estimated at 5 percent demand of available supply. (Cooper, 2002)

Solid Waste
Refuse collection services in Kodiak are provided by the Kodiak Island Borough, which operates a permitted landfill and baler facility. The Kodiak Island Borough Landfill is located at Monashka Bay, about 9.7 kilometers (6 miles) north of the city. (Alaska Department of Community and Economic Development, Division of Community and Business Development, 2002; Alaska Department of Environmental Conservation, 1999) The capacity of the landfill was reached in 1998; however, in November 1999, the Borough completed a vertical and lateral expansion of the landfill, increasing its available capacity (State of Alaska Online, Department of Environmental Conservation, 1999). Residents within the city have home pickup service, while Borough residents have neighborhood dumpsters. Kodiak Sanitation, a private contractor, provides refuse collection services. Kodiak Island Borough also operates a recycling program.

At the time of the 1999 expansion, KLC negotiated a price for dumpster service with the Kodiak Island Borough and Waste Management, Inc. Due to the launch facility's location outside the normal coverage area, the service provided was limited to an 11.5-cubic meter (15-cubic yard) roll-off. During mission status the service is on a monthly basis, and during non-mission status the service is quarterly. (Cooper, 2002)
3.1.13 VISUAL AND AESTHETIC RESOURCES—KODIAK LAUNCH COMPLEX

3.1.13.1 Region of Influence

The Proposed Action site is on Narrow Cape, which is in a relatively remote area of Kodiak Island. The ROI for visual and aesthetic resources is that area surrounding KLC including land area and adjacent ocean area.

Alternative locations for remote telemetry sites in Alaska would include Pasagshak Point, Kenai, Homer, Soldotna, King Salmon, Adak, Cordova, and Pillar Mountain. Activities at these locations would be short-term and temporary. Sites would consist of several instrumentation trailers and at least two mobile antennas. Because of the portable and temporary nature of the activities, the potential for impacts to visual resources is expected to be minimal and therefore will not be discussed further in this document.

3.1.13.2 Affected Environment

Kodiak Island consists primarily of mountainous terrain, with most mountain peaks ranging from 914 to 1,219 meters (3,000 to 4,000 feet) high. About 40 small cirque glaciers are evident along the main ridge of the mountains, which runs northeast to southwest. Canyons radiate from the central divide, many of which have relatively short, swift streams. Exposed bedrock and shallow soils predominate along the rugged coastline. Northwest Kodiak Island has long, narrow fjords and U-shaped valleys, whereas southwest Kodiak Island has few bays and long, continuous shorelines, some with sandy beaches.

Habitat distribution on Kodiak Island is related to differences in elevation. Unconsolidated material is generally absent at very high elevations. Alpine vegetation occurs in mountainous areas below the peaks. Dense shrub and ground cover occurs on steep slopes below 914 meters (3,000 feet) in elevation. Lower slopes and valley floors are covered by sand, gravel, and volcanic ash.

The Narrow Cape area of Kodiak Island, in the vicinity of KLC, has low, grass-covered mountains that level off into a plateau. The mountains are covered with wild flowers in seasons, with patches of Sitka spruce, alder, and willow. Bedrock beaches border the plateau and include Fossil Beach. Barrier beaches and lagoon systems dominate the eastern shoreline, creating a long strip of sandy beaches.

Vegetation colors in the vicinity of KLC range from green to brown, and snow often covers the ground during the winter, although snow cover normally does not last more than a week. At a distance, the mountainous background appears as a darker brown. The climate at KLC has not been well documented; however, it is expected to be similar to the City of Kodiak, where clouds cover an average of 70 percent of the sky throughout the year and the sky is completely overcast about 50 percent of the time. As a result, the sky is often gray.

The varied terrain, extensive vegetative cover, and generally scenic shorelines all contribute to a high visual quality for much of Kodiak Island. The Narrow Cape area has been previously disturbed by commercial launch facilities, a ranch, and a U.S. Coast Guard facility. KLC has several existing structures that could be used to support the GMD program. Existing facilities include two launch pads, a Payload Processing Facility and Launch Control Center, Spacecraft
Assemblies Transfer Facility, and an Integration and Processing Facility (figures 2.3.1-2 through 2.3.1-4). Aside from the existing buildings and structures associated with KLC, man-made structures in the area include the U.S. Coast Guard’s 190-meter-high (625-foot-high) Loran-C navigation transmitter tower and associated white-colored buildings, a few buildings associated with ranching, a complex of buildings associated with World War II activities, and unimproved roads.

Narrow Cape is in a relatively remote area of Kodiak Island. Potentially concerned persons who may have views of KLC include recreational users (fishers, hunters, hikers, etc.); employees and visitors at the Loran-C station, Kodiak Ranch, and KLC; and passengers on offshore vessels. Pasagshak State Recreation Area, a small park containing seven campsites, is about 10 kilometers (6 miles) northwest of Narrow Cape. Approximately a dozen small vacation homes are located in the Pasagshak Bay area. The Kodiak Island Highway, which runs from Kodiak to Narrow Cape, is primarily undeveloped.

3.1.14 WATER RESOURCES—KODIAK LAUNCH COMPLEX

Potentially affected water resources include freshwater surface and groundwater resources and marine waters in the ROI described in the next section. Potential changes in the availability of water supplies as a result of project water use requirements also are addressed. As required by Executive Order 11988, Floodplain Management, potential effects to floodplains were considered; however, none of the proposed facilities in any of the action alternatives would be constructed in a floodplain and further analysis of such issues is not warranted. Potentially affected wetland resources are described in section 3.1.3.

Appendix B includes a description of the primary laws and regulations regarding water resources.

3.1.14.1 Region of Influence

The water resource ROI includes those surface water bodies (streams, lakes and saltwater-influenced lagoons), drainage areas, and groundwater resources that may be affected by the project’s construction or operations. Figure 3.1.14-1 shows the major water bodies near KLC that could be affected along with related water quality sampling points discussed in section 3.1.14.2. These water bodies include Barry Lagoon, Twin Lakes, Triple Lakes, and a number of unnamed streams near KLC. Interceptors launched from KLC could also affect the Pacific Ocean in areas below target interception points, or in other areas between KLC and the target point if interceptors unexpectedly do not reach their targets.

Remote telemetry sites in Alaska are also being considered for the Proposed Action. Activities in these locations would use existing paved or gravel areas and would be short-term, temporary activities. Therefore, the potential for impacts on water resources is minimal and the affected environment in these areas is not discussed further.
3.1.14.2 Affected Environment

Surface Water and Groundwater Resources

Kodiak Island has a marine climate with many natural streams, lakes, and lagoons. Precipitation is common and typically occurs in all months of the year; average precipitation was reported in the 1995 Environmental Baseline of Narrow Cape as 188.57 centimeters (74.24 inches) per year (Alaska Aerospace Development Corporation, 1995b). Streams near KLC are relatively short (generally less than 3.2 kilometers [2 miles] in length) and steep, and they have an average discharge of less than 1.3 cubic meters (46 cubic feet) per second (Alaska Aerospace Development Corporation, 1995b). The major lakes in the ROI are shown in figure 3.1.14-1; West and East Twin Lakes are shallow, freshwater lakes while Triple Lakes and Barry Lagoon are saltwater-influenced lagoons. While some water-bearing zones have been found in underlying bedrock in the ROI, most of the groundwater in the coastal area near KLC is in an unconfined aquifer composed of sand and gravel. Information concerning potential groundwater yields is not available. (Alaska Aerospace Development Corporation, 1995b)

Water Quality

Water quality in the ROI is generally good, and water quality sampling has shown that water quality in the vicinity of KLC is within historical ranges for Kodiak Island as a whole (Alaska Aerospace Development Corporation, 1995b). Water quality samples were taken at the locations shown in figure 3.1.14-1 during 1994, and the key results of this sampling are shown in table 3.1.14-1. In addition, an analysis of surface water collected at East Twin Lake and Triple Lakes (Alaska Aerospace Development Corporation, 1995b) showed that none of the following contaminants were present: volatile organic compounds, pesticides/herbicides, PCBs, nitrates or nitrites, gross alpha radioactivity, total cyanide, and most metals of concern. However, two metallic elements were found: cadmium and beryllium. Cadmium was found in both East Twin Lake and Triple Lakes at a concentration of 0.1 microgram per liter, and beryllium was detected in Triple Lakes at a concentration of 0.9 microgram per liter (Alaska Aerospace Development Corporation, 1995b). These levels of cadmium and beryllium are both below the EPA’s national water quality criteria for the protection of aquatic organisms (the standards are 0.25 and 5.3 micrograms per liter, respectively and assuming a hardness of 15 milligrams of calcium carbonate per liter for the cadmium criterion) (Federal Aviation Administration, 1996). The cadmium concentrations were both well below the 5.0 micrograms per liter maximum contaminant levels allowed by the EPA and the State of Alaska’s drinking water regulations (Federal Aviation Administration, 1996). In the absence of any human-related sources, it is assumed the cadmium and beryllium are from natural sources. The sampling also found coliform bacteria levels in East Twin Lake and Triple Lakes that exceed the “no detect” criteria of the State of Alaska drinking water regulations; therefore, drinking water would require some treatment before it could be used. The likely sources of the bacteria are the bison, cattle, and horses that are raised on the nearby ranch. (Alaska Aerospace Development Corporation, 1998)

Water Use

The primary potable water sources for existing KLC operations are wells on KLC. West and East Twin Lakes have been used for construction water. The potable water supply system has a designed capacity of about 13,060 liters (3,450 gallons) per day; demand is currently estimated at 50 percent of available supply during mission status and 5 percent of available supply when not in mission status (Cooper, 2002). Section 3.1.12 provides more information about KLC utilities,

3.1.15 SUBSISTENCE—KODIAK LAUNCH COMPLEX

Many families living in rural areas of Alaska are partially or wholly dependent upon the harvesting of natural resources for food and other living necessities. The Alaska National Interest Lands Conservation Act of 1980 provides for the continued opportunity for customary and traditional uses of fish and wildlife for subsistence.
In rural communities, the harvesting of subsistence resources can be the primary means of support for a family unit. While food is the primary use of subsistence resources, there are many other uses for subsistence products such as clothing, food for work animals, fuel, home crafts, customary trade, ceremonial tools, as well as arts and crafts. In addition to the material importance of subsistence hunting, it also plays a strong role in the social and cultural traditions of many native Alaskan communities. (Ballistic Missile Defense Organization, 2000)

3.1.15.1 Region of Influence
The ROI for subsistence is the area adjacent to and including Narrow Cape.

3.1.15.2 Affected Environment
Major villages found on Kodiak Island include Akhiok, Karluk, Larsen Bay, Old Harbor, Ouzinkie, and Port Lions. These communities are accessible from Kodiak only by air or water. The populations of these communities range from 80 (Akhiok) to 237 (Old Harbor) and all are 63 percent or more native (table 3.1.15-1). The natives are mainly Alutiiq. Section 3.1.4.2 includes a description of native populations and traditional resources. Commercial fishing is the main source of cash income in these communities, and subsistence is another important activity economically as well as culturally. The percentage of households that use subsistence resources is high in all communities, averaging approximately 99 percent (Ballistic Missile Defense Organization, 2000).

Source: U.S. Census Bureau, 2002

A small number of Old Harbor residents use the coastal and adjacent inland areas around Narrow Cape for subsistence. Salmon, halibut, crab, waterfowl, seal, sea lion, and deer are the primary species harvested by these residents. Other inhabitants of Kodiak Island also engage in subsistence activities. The primary areas for subsistence used by Kodiak residents are the Buskin River, which is adjacent to the Kodiak Airport, and the Afognak and Litnik Rivers, which are both on Afognak Island. The Narrow Cape area is used primarily for harvesting deer and freshwater fish in the vicinity of Twin Lakes. The potential for subsistence use growth of the Narrow Cape area is limited since it is currently being used as a working ranch and as the site of KLC.
3.2 MIDWAY

Although Midway was an alternative site in the Draft EIS, MDA has determined that it is no longer a reasonable alternative and will not be a proposed site for ETR activities. The IDT on-board the SBX would perform the function that had been planned for Midway. The discussion of Midway has been retained in the Final EIS, however, in order to preserve the work that has already been performed.

The proposed GMD ETR activities could have an effect on air quality, biological resources, and hazardous materials and waste at Midway. These resource areas are summarized in the following sections.

Areas that are not expected to be affected sufficiently at Midway to warrant further discussion in this section include airspace, cultural resources, geology and soils, health and safety, land use, noise, socioeconomics, transportation, utilities, visual and aesthetic resources, water resources, and environmental justice. Proposed activities at Midway would not affect controlled and uncontrolled airspace, Special Use Airspace, en route airways and jet routes, or airfields. While many of the islands at Midway Atoll have important historic resources, many of them relating to battles during World War II, there are not expected to be any ground disturbing activities within areas where these resources are located. While proposed construction activities at Sand Island will result in limited clearing and excavation of pad, roadway and cable alignments, it is not expected to create any adverse erosion effects to geology or soils, due primarily to the flat relief and highly permeable nature of the coral soils and artificial (coral rubble) fill. Consequently, this section will not include further analysis of geological resources. Construction and operation activities would follow standard health and safety guidelines. Land use impact would be minimal since the proposed activities would occur in paved areas and would not produce a change in land utilization. No sensitive receptors would be disturbed by the proposed intermittent and short-term activity, and noise levels are expected to be below OSHA workplace standards. As a result of its isolation, limited population, minute local economic activity, and limited GMD ETR activities, socioeconomic impacts would not occur. The few additional personnel would not affect the utilities infrastructure or transportation. Visual and aesthetic resource impacts would be avoided by actions taking place in secure locations that are somewhat hidden by vegetation. The water resources requirements for the proposed activities would result in a minor increase above the existing usage levels, but below past usage levels. An Environmental Justice impact would be a long-term health, environmental, cultural, or economic effect that has a disproportionately high and adverse effect on a nearby minority or low-income population, rather than all nearby residents. No adverse long-term impacts have been identified at Midway. As such, there would be no disproportionately high and adverse human health or environmental effects on the minority or low-income populations.

3.2.1 AIR QUALITY—MIDWAY

Appendix B includes a general description of air quality and the main regulations and laws that govern its protection.
3.2.1.1 Region of Influence

For inert pollutants (all pollutants other than ozone and its precursors), the ROI is generally limited to an area extending no more than a few tens of kilometers (miles) downwind from the source.

The ROI for ozone may extend much further downwind than the ROI for inert pollutants; however, as the project area has no heavy industry and very few automobiles, tropospheric ozone and its precursors are not of concern. Consequently, for the air quality analysis, the ROI for project operational activities includes the area surrounding Sand and Eastern Islands of Midway.

3.2.1.2 Affected Environment

Climate

Due to its low topographic profile and small size, Midway Atoll does not affect its own climate. The climate of Midway Atoll is semi-tropical oceanic, consisting of two distinct seasons. The months from December to February tend to be cool, windy and wet, with the temperature dropping into the low 10s °C (60s °F), while May through October tend to be warm and sunny, with most days reaching the high 20s °C (80s °F).

Midway experiences frequent, but modest, rainfall. It rains, on average, approximately 165 days a year, and the mean annual rainfall is 107 centimeters (42 inches). Since 1918, a minimum annual rainfall of 64 centimeters (25 inches) and a maximum annual rainfall of 175 centimeters (69 inches) have been recorded.

East-northeasterly tradewinds, averaging about 19 kilometers per hour (10 knots), are predominate from March through November, and are generally accompanied by fair weather. From November through February, the weather can be quite variable, ranging from southwesterly winds accompanied by rain and squalls, to gale-force northerly winds. Midway is well north of any hurricane areas and has not been struck by a hurricane in recorded history. (Pacific Division, Naval Facilities Engineering Command, 1994)

Regional Air Quality

No ambient air quality monitoring data is available for the Midway Atoll; however, there are no air pollution problems at Midway, due to the lack of air emissions and sources, and given the amount of strong trade winds. These trade winds quickly disperse any local emissions.

Existing Air Emissions

Current facilities that may emit air pollutants include the carpenter shop, spray paint shop, power plant, boilers, open burning of solid waste at landfills, and open burning of waste oil. Other emissions are from automobiles, small motorized equipment, airplanes, and power boats. (U.S. Department of the Interior, Fish and Wildlife Service, 1996)
3.2.2 BIOLOGICAL RESOURCES—MIDWAY

Appendix B includes a definition of biological resources and the main regulations and laws that govern their protection.

3.2.2.1 Region of Influence

The ROI includes areas on Midway Island that may be affected by construction and operation of an IDT and two COMSATCOM terminals.

3.2.2.2 Affected Environment

Vegetation

Over 200 plant species have been introduced to Midway’s islands since the arrival of permanent residents in 1902. The most common of these include ironwood, golden crown-beard, wild poinsettia, Haole koa, sweet alyssum, buffalo grass, peppergrass, and Bermuda grass. Ironwood trees can grow as much as 12 meters (40 feet) in 18 months unless aggressively managed. Efforts have been undertaken to prevent further colonization, especially in beach areas, to preserve the remaining beach strand vegetation (Pacific Division, Naval Facilities Engineering Command, 1994). Golden crown-beard grows so quickly that it can exclude birds from otherwise desirable nesting habitat. (U.S. Fish and Wildlife Service, Midway Atoll National Refuge, 2002)

Plants indigenous or naturalized to Midway Atoll include beach naupaka, tree heliotrope, beach morning glory, lovegrass, sickle grass, ihi, alena, puncture vine (nohu), and ‘ena’ena. Ihi occurs commonly on Eastern and Spit Islands but is much less common on Sand Island. (U.S. Fish and Wildlife Service, 2002a)

Beach naupaka and tree heliotrope are examples of beach strand vegetation, which are dune-binding species. Although once abundant over much of the coastal areas of Sand Island, these plants have been reduced in extent due to grazing by rats and shading by ironwood trees. Frigate Point on Sand Island contains the only large stand of beach naupaka. (Pacific Division, Naval Facilities Engineering Command, 1994)

Threatened and Endangered Plant Species

No threatened or endangered plant species are located on Midway Atoll.

Wildlife

A large variety of wildlife occurs on Midway Atoll, including an abundance of migratory seabirds. Over 100 species of birds have been identified. About 15 species of birds nest on Midway Atoll with a total population of almost 2 million. Midway has the world’s largest colony of Laysan albatross, nearly 400,000 nesting pairs, and the largest colonies of red-tailed tropicbirds, black noddies, and white terns. Additional bird species include short-tailed and black-footed albatross; shearwaters; brown, masked, and red-footed booby; brown noddys; and terns. Birds native or indigenous to Midway include a small variety of arctic nesting shorebirds, such as the bristle-thighed curlew and ruddy turnstone, and vagrant species observed in small numbers. (U.S. Fish and Wildlife Service, Midway Atoll National Wildlife Refuge, 2002)
An introduced species that has had a profound adverse affect on Midway’s wildlife is the black rat. Due to a very aggressive rat control program, rats have been eliminated from Eastern and Spit islands and are probably also absent from Sand Island. (U.S. Fish and Wildlife Service, Midway Atoll National Wildlife Refuge, 2002)

About 250 spinner dolphins inhabit the lagoon during the day and generally leave it each night to feed in deeper waters. The lagoon also supports over 130 species of fish and a variety of marine invertebrates (U.S. Department of the Interior, Fish and Wildlife Service, 1996)

**Threatened and Endangered Wildlife Species**

The endangered short-tailed albatross (*Phoebastria albatrus*) is a visitor to Midway during its migration, and single nests occasionally occur on the island (U.S. Fish and Wildlife Service, Pacific Region, 2002b).

Approximately 45 to 55 endangered Hawaiian monk seals (*Monachus schauinslandi*) live on Midway Atoll. Eastern and Spit islands are the main pupping areas. The monk seal is endemic to the Hawaiian archipelago and is found almost exclusively in the Northwestern Hawaiian Islands. A number of threatened green sea turtles (*Chelonia mydas*) live and forage within Midway’s lagoon. Nesting has not been recorded on Midway Atoll. (U.S. Fish and Wildlife Service, 2002a) The endangered hawksbill sea turtle (*Eretmochelys imbricata*) is a rare visitor to Midway (Pacific Division, Naval Facilities Engineering Command, 1994). Current rules on Midway require that people stay at least 31 meters (100 feet) from monk seals on the beach and from basking sea turtles (U.S. Fish and Wildlife Service, 2002a).

**Environmentally Sensitive Habitat**

All of Midway Atoll, except for Sand Island and its harbor, has been designated as critical habitat for the Hawaiian monk seal. A small (less than 0.2 hectare [0.5 acre]), emergent wetland area has been identified on Sand Island. It is located west of Decatur Avenue, north of the cemetery, and south of Halsey Drive. (Pacific Division, Naval Facilities Engineering Command, 1994)

The *[Coral Reef Ecosystem Fishery Management Plan](#)* for the western Pacific has established Marine Protected Areas. No-take Marine Protected Areas are at 0- to 10-fathom (0- to 18-meter [60-foot]) depths for all the chain. No-take Marine Protected Areas are also located from 10 to 50 fathoms (18 to 91 meters [300 feet]) at French Frigate Shoals, Laysan, and the northern half of Midway. The southern half of Midway is for recreational catch and release only. (American Association for the Advancement of Science, 2002)

### 3.2.3 HAZARDOUS MATERIALS AND HAZARDOUS WASTE—MIDWAY

Appendix B includes a general description of hazardous materials and waste.

#### 3.2.3.1 Region of Influence

The ROI for potential impacts related to hazardous materials/wastes includes areas of the atoll to be used for communications operations, and in areas where hazardous materials are stored and handled.
3.2.3.2 Affected Environment

The U.S. Navy closed Naval Air Facility Midway in 1993 and turned control of Midway Atoll over to the USFWS in 1997. USFWS manages the location as the Midway Atoll National Wildlife Refuge. Essential facilities services are provided by a contractor.

There is currently no military presence on Midway Atoll. Pollution Prevention/Recycling/Waste Minimization would be practiced in accordance with EPA, DoD, and Army requirements. IRP activities were conducted by the U.S. Navy in the early- to mid-1990s under the Comprehensive Long-Term Environmental Action Navy (CLEAN) program. IRP sites 72, 77, and 79 are at the proposed IDT and COMSATCOM location. These IRP sites were identified as areas where only POL releases had occurred in the past. IRP Site 50 was a formerly contaminated with hazardous material, but all remedial actions were completed. (Naval Facilities Engineering Command, Pacific Division, 1997)

Currently, Midway has two 7.95-million-liter (2.1-million-gallon) jet petroleum #5 (JP-5) storage tanks and five 25,170-liter (66,500-gallon) motor gasoline (MOGAS) tanks. In addition, there are five tank truck refuelers, 2,745 meters (9,000 feet) of fuel spill boom and skimmer/vacuum truck. The USFWS reports an average of approximately 643,520 liters (170,000 gallons) of JP-5 and 11,356 liters (3,000 gallons) of MOGAS usage per month. (U.S. Fish and Wildlife Service, 2002a)

All known USTs and POL pipelines were removed by the U.S. Navy under the CLEAN program. (Naval Facilities Engineering Command, Pacific Division, 1997)

Asbestos remediation/removal was conducted at Midway by a U.S. Navy contractor in the mid-1990s. Lead-based paint was assessed in all buildings and structures on Sand and Eastern Islands. PCB removal activity was initiated by the U.S. Navy in 1984. By September 1996, removal activity was substantially complete. (Naval Facilities Engineering Command, Pacific Division, 1997)

Aviation jet fuel is used for transportation of personnel to and from the atoll, in support of USFWS service activities.

Small quantities of nonhazardous and hazardous wastes generated at Midway may include batteries, waste oil, fuels, paints, cleaners, spill cleanup materials, and empty containers.
3.3 REAGAN TEST SITE

The existing environment at RTS was described in the Final Supplemental EIS for Proposed Actions at USAKA (U.S. Army Space and Strategic Defense Command, 1993a). For the most part, that description is still accurate and will not be repeated in this document. Rather, for resources that may be affected by ETR activities at RTS, the pertinent resource discussions will be summarized and any differences in existing environmental conditions, including new facilities or infrastructure, will be noted. The more detailed discussion in the Final Supplemental EIS is incorporated by reference and will be made available for review by those who wish more information concerning the existing environment at RTS.

The RTS environmental program is governed by the Environmental Standards and Procedures for the U.S. Army Kwajalein Atoll (USAKA) Activities in the Republic of the Marshall Islands, unofficially called the UES. The UES is mandated in the Compact of Free Association between the Republic of the Marshall Islands and the United States as approved by U.S. Public Law 99-239. They became effective 4 December 1995. The UES is a one-of-a-kind regulatory program document with substantively similar U.S. and RMI statutes and regulations. As required in the UES, RTS issues Documents of Environmental Protection, similar to federal and state permits, for conducting activities with potential to affect the environment. The Documents of Environmental Protection are streamlined environmental protection documents for specific environmental activities (e.g., air emissions from major stationary sources; construction and operation of power plants; point source discharges) that specify in detail how UES compliance will be maintained. The Documents of Environmental Protection are tailored specifically for conditions and considerations at RTS (U.S. Army Space and Missile Defense Command, 2001a).

The proposed ETR activities could have an effect on air quality, airspace, biological resources, hazardous materials and waste, health and safety, and utilities at RTS. These resource areas are summarized in the following sections.

Areas that are not expected to be affected sufficiently at RTS to warrant further discussion in this section include cultural resources, geology and soils, land use, noise, socioeconomics, transportation, water resources, visual and aesthetic resources, and environmental justice. While many of the islands at Kwajalein Atoll have important historic resources, many of them relating to battles during World War II, there are not expected to be any ground disturbing activities within areas where these resources are located. Consequently, this section will not include further analysis of cultural resources. While proposed GBI and target launch activities would result in minor soil contamination from rocket emissions in and around the designated Launch Hazard Area at Meck, they are not expected to create adverse effects beyond those previously analyzed in the USAKA Supplemental EIS (U.S. Army Space and Strategic Defense Command, 1993a). Use of existing range radars and minor construction upgrades to GBI and radar facilities will have no adverse effects on site soils. Consequently, this section will not include further analysis of geological resources. Land use at RTS and surrounding areas would not change. Utilization of adjacent lands would be consistent with existing land use agreements. The existing noise levels at RTS would continue, including those associated with proposed missile launches. None of the noise levels outside of the Ground Hazard Area boundary for the proposed launch areas where non-essential personnel and the public are excluded would exceed either DoD or OSHA safety requirements. Personnel within the Ground Hazard Area wear hearing protection devices. Due to RTS’s isolation, and a population
consisting exclusively of RTS employees and support contractors and their families, GMD ETR activities would not produce any adverse socioeconomic impacts. Shipping of project-related materials, as well as transportation of personnel, would utilize air, roadway, and shipping/ferrying routes that are equipped to handle both the loads and frequency of project demands. These actions are considered typical and a routine activity.

Although the visual resources on RTS may be considered significant by some viewers, much of the area is already developed with the types of structures and activities that are being considered in the Proposed Action. Therefore, this section does not include further analysis of visual resources at RTS. An Environmental Justice impact would be a long-term health, environmental, cultural, or economic effect that has a disproportionately high and adverse effect on a nearby minority or low-income population, rather than all nearby residents. No adverse long-term impacts have been identified at the proposed RTS sites. As such, there would be no disproportionately high and adverse human health or environmental effects on the minority or low-income populations that may be present in the vicinity of those locations.

### 3.3.1 AIR QUALITY—REAGAN TEST SITE

The UES regulate air quality at RTS. These standards are based upon the U.S. Clean Air Act and its promulgated regulations, but do not include many of the procedural and technology based requirements. The standards are designed to maintain the current air quality at RTS. Pollutant ambient air concentrations may not increase above the baseline level by more than an increment of 25 percent of the applicable Ambient Air Quality Standards (AAQS). The UES AAQS are set at 80 percent of the NAAQS provided in appendix B. The UES requires a Document of Environmental Protection, similar to an operating permit in the United States, for all new major stationary sources, or sources regulated under the U.S. National Emissions Standards for Hazardous Air Pollutants. Existing sources at RTS are covered by the Air Emissions from Major Sources at USAKA/KMR Document of Environmental Protection, as revised November 2000. This Document of Environmental Protection establishes operational requirements and limitations for sources at RTS.

#### 3.3.1.1 Region of Influence

For inert pollutants (all pollutants other than ozone and its precursors), the ROI is generally limited to an area extending no more than a few tens of miles downwind from the source.

The ROI for ozone may extend much further downwind than the ROI for inert pollutants; however, as the project area has no heavy industry and very few automobiles, tropospheric ozone and its precursors are not of concern. For the air quality analysis, the ROI for project operational activities includes Kwajalein, Meck, Eniwetak, and Omelek islands. However, the ROI also includes areas that may potentially be affected by the use of RTS for the SBX, including the mooring sites identified in section 2.3.1.3.

#### 3.3.1.2 Affected Environment

Because of the relatively small numbers and types of air pollution sources, the dispersion caused by trade winds, and the lack of topographic features that inhibit dispersion, air quality at RTS is considered good (i.e., well below the maximum pollution levels established for air quality in the United States). (U.S. Army Space and Missile Defense Command, 2001a)
Kwajalein

Climate

Kwajalein Atoll is located less than 1,000 kilometers (600 miles) north of the equator and has a tropical marine climate characterized by relatively high annual rainfall and warm to hot, humid weather throughout the year. The mean annual temperature at Kwajalein is 28°C (82°F). The average annual precipitation is 256 centimeters (101 inches). The main rainfall season lasts from mid-May to mid-December, with about 30 centimeters (10 inches) of rainfall per month. Kwajalein’s relative humidity averages between 70 and 85 percent throughout the year. Virtually constant cloud cover, light easterly winds, and frequent moderate to heavy rain showers prevail during the wet season.

Trade winds are dominant throughout the year and strongest from November to June. The prevailing winds blow from the east to the northeast with an average speed of 26 kilometers (16 miles) per hour in the winter and 10 kilometers (6 miles) per hour in the summer.

Regional Air Quality

The ambient air on Kwajalein was analyzed in a U.S. Army Environmental Hygiene Agency study completed in 1993. This testing was conducted before the adoption of the UES and its unique UES AAQS. In this study the concentration of criteria pollutants was measured both upwind and downwind of power plants 1A and 1B (table 3.3.1-1). The concentrations of sulfur dioxide, lead, and particulate matter with an aerodynamic diameter of less than or equal to 10 micrometers (PM-10) were found to be below their NAAQS. Since there is no short-term NAAQS for nitrogen dioxide, the study compared the measured concentrations at Kwajalein to the 1-hour California AAQS for nitrogen dioxide; the concentrations at Kwajalein were below this standard. The concentrations measured at Kwajalein were below the 1-hour NAAQS for carbon monoxide, but downwind concentrations were greater than the 8-hour NAAQS for carbon monoxide. (U.S. Army Environmental Hygiene Agency, 1993)

*As no short-term NAAQS exist for nitrogen dioxide, the California Ambient Air Quality Standard was used for comparison.
Existing Emissions Sources
Ambient air quality is generally characterized as good due to the relatively small number of air pollution sources and because of good dispersion produced by the strong, persistent tradewinds and lack of topographic features to inhibit pollution dispersion. The power plants are the primary source of air emissions on Kwajalein. The concentration of the criteria air pollutants was measured both upwind and downwind of power plants 1A and 1B. The concentrations of sulfur dioxide, lead, and PM-10 were found to be below their UES AAQS both upwind and downwind. Since there is no short-term UES AAQS for nitrogen dioxide, the study compared the measured concentrations at Kwajalein to the 1-hour California AAQS for nitrogen dioxide; the concentrations at Kwajalein were below this standard. The concentrations measured at Kwajalein were below the 1-hour UES AAQS for carbon monoxide, but downwind concentrations were greater than the 8-hour UES AAQS for carbon monoxide.

The existing primary pollution sources include power plants (1A and 1B), fuel storage tanks, solid waste incinerators, diesel fired commercial boilers, a concrete batching plant, and transportation. Rocket launches tend to be smaller sources of emissions. USAKA performs an Air Emissions Inventory on a biennial basis in accordance with the UES (table 3.3.1-2).

Meck

Climate
Temperature, rainfall, humidity, and trade winds at Meck are similar to those described for Kwajalein.

Regional Air Quality
The Supplemental EIS for USAKA predicts that Kwajalein Island has far more air pollutant emissions than Meck. Therefore, the ambient air quality is assumed to be comparable to that measured at the upwind location at Kwajalein Island, as listed in table 3.3.1-1.

Existing Emission Sources
Existing pollution sources for Meck are similar to those listed for Kwajalein, including a power plant, a solid waste incinerator, fuel storage tanks, and transportation. Infrequent rocket launches also occur on Meck. Table 3.3.1-3 summarizes air emissions on Meck.

Rocket launch emissions are also considered to be sources of pollutants, which result in short term, temporary increases in pollutants. Table 3.3.1-4 lists the estimated rocket launch emissions per year for a high level of activity according to the Final Supplemental EIS for Proposed Actions at USAKA (U.S. Army Space and Strategic Defense Command, 1993a). For Meck, the estimated number of launches was 28 per year for Strategic Launch Vehicles (assuming the use of SR-19 rocket motors).

Roi-Namur

Climate
The climate of Roi-Namur is similar to that described for Kwajalein.

Regional Air Quality
The Supplemental EIS for USAKA predicts that air pollution emissions on Roi-Namur are comparable to those on Kwajalein; therefore, air quality on Roi-Namur is expected to be comparable to that of Kwajalein Island (table 3.3.1-1).

Existing Emission Sources
Existing pollution sources for Roi-Namur are similar to those listed for Kwajalein and Meck, including a power plant, a solid waste incinerator, fuel storage tanks and transportation on the island. RTS constructed a new power plant on Roi-Namur, bringing it online in 2002. Air quality requirements for the plant were established in a May 1999 Document of Environmental Protection entitled: Construction and Operations of Power Plant Demolition of Existing Power Plant, Roi-Namur. Table 3.3.1-5 summarizes air emissions on Roi-Namur.

3.3.2 AIRSPACE—REAGAN TEST SITE

Appendix B includes a general description of airspace.

3.3.2.1 Region of Influence

The ROI for airspace at RTS includes the airspace over and surrounding the potential radiation hazard areas that extend from the mooring location north of Kwajalein in the USAKA lagoon (figure 3.3.2-1).

3.3.2.2 Affected Environment

Controlled and Uncontrolled Airspace

RTS is located in international airspace. Therefore, the procedures of the International Civil Aviation Organization (ICAO) outlined in ICAO Document 4444, *Rules of the Air and Air Traffic Services*, are followed (International Civil Aviation Organization, 1996; 1997). ICAO Document 4444 is the equivalent air traffic control manual to the FAA Handbook 7110.65, *Air Traffic Control*. The ICAO is not an active air traffic control agency and has no authority to allow aircraft into a particular sovereign nation’s Flight Information Region or Air Defense Identification Zone and does not set international boundaries for air traffic control purposes. The ICAO is a specialized agency of the United Nations whose objective is to develop the principles and techniques of international air navigation and to foster planning and development of international civil air transport.

The FAA acts as the U.S. agent for aeronautical information to the ICAO, and air traffic in the ROI is managed by the Oakland ARTCC in its Oceanic Control-6 Sector, the boundaries of which are shown in figure 3.3.2-2.

Special Use Airspace

There is no special use airspace in the ROI.

En Route Airways and Jet Routes

Although relatively remote from the majority of jet routes that cross the Pacific, the RTS and vicinity have several jet routes passing nearby, including R-584 and A-222 (figure 3.3.2-1). An accounting of the number of flights using each jet route is not maintained.

Figure 3.3.2-2

GMD ETR Final EIS
Although not depicted on either the North Pacific Route Chart, Southwest Area or Composite, there are low altitude airways carrying commercial traffic between the various islands of the RMI, particularly between the Marshall Islands International Airport at Majuro and Bucholz Army Airfield on Kwajalein.

Airports/Airfields

In 1993 Bucholz Army Airfield had a reported 1,674 operations per month, an average of over 55 per day. Many of the 55 flights per day were aircraft and helicopter flights to other USAKA islands. Currently flight activity through Bucholz Army Airfield is reduced. Dyess Army Airfield on Roi-Namur provides service to a variety of aircraft and helicopters.

3.3.3 BIOLOGICAL RESOURCES—REAGAN TEST SITE

Appendix B includes a general definition of biological resources. Regulations governing endangered species and wildlife resources at RTS are specified in UES Section 3-4. Water quality and reef protection standards at RTS are in UES Section 3-2 (U.S. Army Space and Missile Defense Command, 2001a).

3.3.3.1 Region of Influence

The ROI includes areas on RTS that may be affected by interceptor launches from existing silos, target launches from existing and new launch sites, and the use of existing sensors. The ROI for biological resources includes the entire island and near-shore reef area for islands where target and interceptor missiles would be launched. For islands where only sensors would be placed, the ROI would be limited to the sites where program activities are conducted and the EMR hazard area. The ROI for the flight test corridor includes the missile over-flight area and the potential debris impact areas over the BOA or Kwajalein Lagoon within the Mid-atoll Corridor. The ROI also includes areas that may potentially be affected by the use of RTS for the SBX, including the mooring sites identified in section 2.3.1.3.

3.3.3.2 Affected Environment

Vegetation

The types of vegetation currently found on USAKA consist of managed vegetation, herbaceous (green, leaf-like) strand, littoral (relating to the shore) shrubland, littoral forest, and coconut plantation. Managed vegetation is disturbed vegetation dominated by alien weeds and is usually maintained by mowing. Herbaceous strand is a narrow zone of vegetation on upper sandy or rocky beaches dominated by grasses, sedges, and vines. Littoral shrubland consists of vegetation in coastal areas dominated by wide spread shrubs. Littoral forest is usually the most common type of vegetation on tropical islands dominated often by a single tree species. Coconut plantations are dominated by planted coconut palms. (Oak Ridge Institute for Science and Education and U.S. Army Environmental Center, 1999)

Kwajalein

Much of Kwajalein has been cleared and paved, including the large runway occupying the entire center (southern) portion of the island, and very little undisturbed vegetation remains. Non-native grasses and weeds dominate the open areas and are maintained by mowing. The island
has been enlarged over the years with dredged landfill since the 1930s and consequently exhibits vegetation characteristic of heavily disturbed areas. (U.S. Army Strategic Defense Command, 1989a; U.S. Army Space and Strategic Defense Command, 1993a; 1995)

Most of the managed vegetation on Kwajalein consists of weedy alien plants such as mat grass, coat buttons, temple grass, and Bermuda grass. Some herbaceous strand is found along the coast and is dominated by beach morning glory, hurricane grass, and sickle grass. Tree heliotrope and beach sunflower are examples of littoral shrubland species found on the island. The most common trees on Kwajalein are coconut, screw pine, and ironwood; however, no littoral forest is present. (Oak Ridge Institute for Science and Education and U.S. Army Environmental Center, 1999)

Previously existing lagoon and nearshore marine habitat along the Kwajalein lagoon shoreline has been buried under landfill. However, along the northern edge of the island on the lagoon floor are several small communities of the rare seagrass *Halophila minor*. (U.S. Army Strategic Defense Command, 1989a; U.S. Army Space and Strategic Defense Command, 1993a; 1995)

**Meck**

Much of Meck has been cleared and paved. Non-native grasses and weeds dominate the open areas and are maintained by mowing. A few native trees still exist on the northern end of the island within the ROI. The island has been enlarged with dredged fill material. (U.S. Army Strategic Defense Command, 1989a; U.S. Army Space and Strategic Defense Command, 1993a; 1995)

Vegetation on Meck is mainly managed vegetation with some small patches of herbaceous strand and littoral shrubland. Managed vegetation consists of plants such as coat buttons, mat grass, hurricane grass, and garden spurge. Herbaceous strand vegetation such as mat grass, beach morning glory, and sickle grass tends to occur in areas near the ocean that are no longer mowed. No littoral forest occurs on Meck. (Oak Ridge Institute for Science and Education and U.S. Army Environmental Center, 1999)

**Roi-Namur**

All five vegetation types described above are found on Roi-Namur. Non-native grasses and weeds dominate the open areas of the island and are maintained by mowing. Most of the island is maintained (i.e., open grassy areas, golf course, runway, housing areas) and a sizable portion of the island is used for radar operations, has been recently cleared, and/or is used as a repository for plant debris/compost and is overgrown with vines (e.g., beach sunflower and beach morning glory). Herbaceous strand is found in some coastal areas such as the west end of the runway and is dominated by beach sunflower, hurricane grass, and sickle grass. Littoral shrubland is also found along some of the coast and consists mainly of tree heliotrope and beach naupaka. A small patch of disturbed littoral forest is located in the northwest corner of Roi-Namur. Only a small portion (the southeastern tip) of Roi-Namur has been left relatively undisturbed since World War II. A forested area with coconut palm in the overstory has been allowed to recover on the eastern shore since approximately 1945. Coconut plantation vegetation includes some large patches of beach hibiscus and pisonia. Thick strands of small-leafed mangrove surround a small wetland in the center of the island. Although the harbor area on the lagoon side of the island has been dredged, the area supports the largest known community of the rare seagrass *Halophila minor* at Kwajalein Atoll. (Oak Ridge Institute for
Threatened and Endangered Plant Species

No threatened or endangered plant species have been identified on Kwajalein, Meck, or Roi-Namur. (U.S. Army Space and Strategic Defense Command, 1995; U.S. Army Space and Missile Defense Command, 2001a)

Wildlife

Kwajalein

Numerous small parcels of seabird roosting habitat have been identified on the western end of Kwajalein within the ROI. Large numbers of migrating shorebirds have been observed, including the Pacific golden plover and the ruddy turnstone. (U.S. Army Strategic Defense Command, 1989a; U.S. Army Space and Strategic Defense Command, 1993a; 1995) Since 1996, white terns have been the only seabirds observed breeding on Kwajalein. Black noddies and great crested terns were observed foraging in the main harbor and along the northwestern coastline respectively. (U.S. Department of the Army, 2001)

Five species of giant clam are found at USAKA along the surrounding reef on the lagoon side and ocean side, and between several of the islands. The largest species, the bear's paw or gigas clam (*Tridacna gigas*), which was observed during the 1998 inventory (U.S. Department of the Army, 2001) has been significantly reduced in number, and the Republic of the Marshall Islands (RMI) government and the National Marine Fisheries Service are examining all species for listing as threatened or endangered. (U.S. Army Space and Strategic Defense Command, 1995)

Meck

Seabirds have been observed nesting along the eastern perimeter of the runway on Meck. Habitat for seabird roosting exists to the southwest of the launch site in the fill area at the edge of the ROI. Black-naped terns regularly roost at the southeast corner of the runway. (U.S. Army Strategic Defense Command, 1989a; U.S. Army Space and Strategic Defense Command, 1993a; 1995) Black-naped terns were observed roosting on the southeastern tip of Meck and in active colonies on the east side of the helicopter pad during the 1998 inventory (U.S. Department of the Army, 2001).

Roi-Namur

Nesting terns use the southern tip of Roi-Namur, and assorted shorebirds roost in the shrubs along the western shore. Reef herons feed in the shore flats and tidepools east of the runway and along the eastern shore. The only seabird that appeared to be nesting during the 1998 inventory was the white tern (U.S. Department of the Army, 2001). The forested area on the east side of Roi-Namur supports habitat for a variety of nesting seabirds. (U.S. Army Space and Strategic Defense Command, 1995) Great-crested terns, golden plovers, ruddy turnstones, whimbrels, and grey-tailed and wandering tattlers were observed during the 1998 inventory (U.S. Department of the Army, 2001).
Coconut crabs occur in the forested area on the east side of Roi-Namur. Additional non-avian fauna includes rodents, lizards, and domestic dogs and cats. (U.S. Army Space and Strategic Defense Command, 1995)

**Essential Fish Habitat**

Hundreds of species of coral, as well as 250 species of reef fish, can be found in the atolls of the Marshall Islands. Food cultivation on these islands is limited; as a result, fish and seafood are staples of the Marshallese diet. (Pacific Island Travel, 2002) The multilateral fisheries agreement between the United States and South Pacific island governments, including the Marshall Islands, seeks to protect the fisheries in the Exclusive Economic Zones. This has contributed to the adoption of the United Nations Agreement on Highly Migratory Fish Stocks and Straddling Fish Stocks, a treaty that promotes the long-term sustainable use of highly migratory species, such as tuna, by balancing the interests of coastal states and states whose vessels fish on the high seas. (U.S. Department of State, 2002)

**Threatened and Endangered Wildlife Species**

**Kwajalein**

Sea turtles frequently enter the lagoon and are commonly seen in the harbors at Kwajalein. Green and hawksbill (*Eretmochelys imbricata*) sea turtles have been observed on Kwajalein, but very little sea turtle nesting activity has been documented in recent years. (U.S. Army Space and Strategic Defense Command, 1995)

**Meck**

Sea turtles frequently enter the lagoon and are commonly seen feeding in the waters surrounding Meck. Although some sandy beaches on the lagoon side of Meck provide potential sea turtle nesting habitat, no evidence of nesting has been observed.

**Roi-Namur**

Sea turtles frequently enter the lagoon and are commonly seen in the harbors at Roi-Namur. Some of the sandy beaches of Roi-Namur provide potential nesting habitat for the green and hawksbill sea turtles. At least two instances of nesting have been reported on Roi-Namur in recent years.

Threatened and endangered marine species that may possibly occur in and around USAKA include the blue whale (*Balaenoptera musculus*), finback whale (*Balaenoptera physalus*), humpback whale, sperm whale (*Physeter macrocephalus*), leatherback sea turtle (*Dermochelys coriacea*), loggerhead sea turtle (*Caretta caretta*), olive ridley sea turtle (*Lepidochelys olivacea*), hawksbill sea turtle (*Eretmochelys imbricata*) and green sea turtle (*Chelonia mydas*). These marine mammals and sea turtles are widely distributed, open-water species. (U.S. Army Space and Strategic Defense Command, 1995; U.S. Army Space and Missile Defense Command, 2001a)

**Environmentally Sensitive Habitat**

**Kwajalein**

Extensive dredge and fill activities since the 1930s have degraded the marine habitat surrounding Kwajalein, particularly on the lagoon side. A remnant of the original reef flat is
located just north of Echo Pier, outside the harbor. Despite the lack of natural vegetation, the islet provides limited habitat for several species of birds, particularly migrant shorebirds and waterfowl. (U.S. Army Strategic Defense Command, 1989a; U.S. Army Space and Strategic Defense Command, 1993a; 1995; U.S. Army Space and Missile Defense Command, 2001a)

Meck
Extensive dredging and the deposition of fill on the lagoon reef flat have greatly altered the marine environment of Meck. Most of the island is surrounded by riprap intended for shoreline protection. The only remaining undisturbed reef flats occur at the north and south tips of the island. Giant clams are found on the reef. (U.S. Army Strategic Defense Command, 1989a; U.S. Army Space and Strategic Defense Command, 1993a; 1995)

Roi-Namur
Marine habitat of importance to biological resources on Roi-Namur includes the lagoon-facing and ocean-facing reef slopes and flats, inter-island reef flat, lagoon floor, seagrass beds, and intertidal zone. The reef flats at the east and west ends of Roi-Namur support coral and giant clams but do not exhibit high coral coverage due to the strong current. More active coral growth was observed on the southwestern corner of the island along the lagoon side. The seagrass beds along the lagoon side may serve as a juvenile fish nursery area. (U.S. Army Space and Strategic Defense Command, 1995)

3.3.4 HAZARDOUS MATERIALS AND HAZARDOUS WASTE—REAGAN TEST SITE

Appendix B includes a general description of hazardous materials and hazardous waste laws and regulations. Regulations governing hazardous material and hazardous waste management at RTS are specified in UES Section 3-6.

3.3.4.1 Region of Influence
The ROI for potential impacts related to hazardous materials/wastes would be limited to areas of the atoll to be used for missile launch (Meck) and related communications operations, and in areas where hazardous materials are stored and handled (Kwajalein and Meck islands). Some materials may also be stored or trans-shipped via Roi-Namur. All three islands are part of the East Reef of Kwajalein Atoll.

3.3.4.2 Affected Environment
The affected environment at the RTS is the Kwajalein Lagoon (where the SBX would be moored), the island of Kwajalein (where the GBI would be received and temporarily stored), and Meck, where launch would occur.

Hazardous Materials and Waste Management
The use of hazardous materials at RTS, including Kwajalein Island, is limited primarily to materials used in facility infrastructure support and flight operations, with some additional quantities of hazardous materials used by various test operations at the range. Hazardous materials used in base infrastructure support activities include various cleaning solvents
(chlorinated and non-chlorinated), paints, cleaning fluids, pesticides, motor fuels and other petroleum products, freons (for air conditioning), and other materials. A hazardous materials management plan is prepared for all hazardous materials or petroleum products shipped to RTS. The hazardous materials management plan outlines the procedures for storage, use, transportation, and disposal of the hazardous materials or petroleum products. These substances are shipped to RTS by ship or by air (U.S. Army Space and Missile Defense Command, 2001a). Upon arrival at RTS, hazardous materials to be used by RTS assets are distributed, as needed, to various satellite supply facilities, from which they are distributed to the individual users. Distribution is coordinated through the base supply system; however, the issue of such materials requires prior authorization by the RTS Environmental Office to prevent unapproved uses of hazardous materials. An activity-specific Hazardous Materials Procedure must be submitted to the Commander, RTS for approval within 15 days of receipt of any hazardous material or before use, whichever comes first. Hazardous materials to be used by organizations utilizing the test range and its facilities (i.e., range users) are under the direct control of the user organization, which is responsible for ensuring that these materials are stored and used in accordance with local and federal requirements.

Users provide storage of all materials in accordance with established procedures applicable to individual operations. The use of all hazardous materials is subject to ongoing inspection by RTS environmental compliance and safety offices to ensure the safe use of all materials. The majority of these materials are consumed in operational processes (including small losses to the air and water).

Aircraft flight operations conducted at RTS consist primarily of flights between Bucholz Army Airfield on Kwajalein Island and Dyess Army Air Field at Roi-Namur, as well as flights using RTS as a trans-Pacific stopover. Helicopters also operate at RTS. These flight operations involve the use of various grades of jet propellant, which are refined petroleum products (kerosenes). Fuels are stored in ASTs located at several islands in the USAKA. Fuels are transported to RTS by ship (U.S. Army Space and Missile Defense Command, 2001a). Significant quantities of waste fuels are not normally generated since fuels are used up in power generation, flight operations, marine vessels, and vehicle and equipment usage.

Hazardous or toxic waste treatment or disposal is not allowed at RTS under the UES. Hazardous waste, whether generated by RTS activities or range users, is handled in accordance with the procedures specified in the UES Part 3-6.5. Hazardous wastes are collected at individual work sites in waste containers. These containers are labeled in accordance with the waste which they contain and are dated the day that the first waste is collected in the container. Containers are kept at the point of generation accumulation site until full or until a specified time limit is reached. Once full, containers are collected from the generation point within 72 hours and are prepared for transport to the RTS Hazardous Waste 90-Day Storage Facility (Building 1521), located on Kwajalein Island. Each of the point of generation accumulation sites is designed to handle hazardous waste and provide the ability to contain any accidental spills of material, including spills of full containers, until appropriate cleanup can be completed. For the staging area on Roi-Namur, hazardous wastes are transported on the weekly barge to Kwajalein (Department of Defense, Ballistic Missile Defense, U.S. Space and Missile Defense Command, 1999).

At the 90-Day Storage Facility any sampling of waste is performed (for waste from uncharacterized waste streams), and waste is prepared for final off-island shipment for disposal.
Wastes are shipped off-island within 90 days of arrival at Building 1521 to Honolulu on the supply barge, for treatment and disposal in the continental United States. The barge departs Kwajalein every 4 weeks. Therefore, the facility does not need to qualify for long-term storage under the UES (U.S. Army Space and Strategic Defense Command, 1995).

The UES requires preparation and implementation of a Kwajalein Environmental Emergency Plan for responding to releases of oil, hazardous materials, pollutants, and contaminants to the environment. The Kwajalein Environmental Emergency Plan is a contingency plan similar to a spill prevention, control and countermeasure plan, but which incorporates response provisions of a National Contingency Plan. The hazardous materials management plan is incorporated into the Kwajalein Environmental Emergency Plan.

Pollution Prevention/Recycling/Waste Minimization
Pollution Prevention/Recycling/Waste Minimization activities are performed in accordance with the UES and established contractor procedures in place at RTS.

Installation Restoration Program
The IRP is not applicable to RTS, since it is located in a foreign country (the RMI). Remedial action is performed as needed, in accordance with the UES.

Underground and Aboveground Storage Tanks
A number of active ASTs are located on RTS. Bulk fuel capacity (diesel, MOGAS, and JP-5) on Kwajalein is approximately 38 million liters (10 million gallons). Full capacity is rarely used. The few remaining USTs are in the process of being removed. Installation of new USTs is prohibited.

Asbestos, Lead-Based Paint, and Polychlorinated Biphenyls
All areas containing asbestos are identified by signs in English and Marshallese. Asbestos-containing materials are used and maintained in accordance with the provisions of the UES and hazardous materials management plan. Any asbestos abatement activities would be conducted in accordance with the UES. Incineration, landfilling, or disposal of asbestos-containing materials at RTS is prohibited.

Existing areas containing lead-based paint are maintained according to established RTS safety procedures. Lead-base paint abatement activities are also conducted according to established procedures and monitored by the RTS Logistics Contractor Industrial Hygiene staff. Lead-based paint hazardous waste is shipped to the continental United States for disposal at a permitted treatment, storage, or disposal facility.

All existing areas or locations that contain PCBs or PCB equipment are regularly inspected and maintained in accordance with the UES and hazardous materials management plan. New uses of PCBs and the introduction of PCBs, PCB articles, or PCB items are prohibited. Incineration, landfilling, or disposal of PCBs or PCB items is prohibited.
Liquid Propellants and Other Toxic Fuels
Existing procedures assure safe handling of liquid propellants and other toxic materials. Current operations include storage and handling of GBI and EKV propellants.

3.3.5 HEALTH AND SAFETY—REAGAN TEST SITE
Appendix B includes a general description of health and safety.

3.3.5.1 Region of Influence
The ROI for potential impacts to worker health and safety at the RTS is greatest in the areas where missile components are stored and handled (Kwajalein and Meck Islands) and where launch (Meck) and post-launch activities occur.

The worker population of concern for the Proposed Action includes all of RTS, but would predominantly consist of the contractor, military and government civilian personnel directly involved with GMD ETR program operations.

The ROI for potential impact to public health and safety encompasses all 11 USAKA islands and other islands at Kwajalein Atoll and nearby atolls that could be affected by GMD ETR Program activities including pre-launch transport of missile components, missile launch, and missile flight. A launch failure could potentially involve an explosion, missile debris, release of toxic materials into the air or water, high noise levels, and/or fire. The population of concern for the Proposed Action consists of the community living on the various atolls and low-lying islands that comprise the RMI.

The ROI for EMR human health effects includes an area up to 85 meters (280 feet) from the SBX platform. The ROI for certain electronic equipment and civilian aircraft includes an area up to 19 kilometers (11.8 miles) from the SBX platform.

3.3.5.2 Affected Environment
Range Safety
RTS has the unique mission of serving as the target for a wide variety of missile launch operations from Vandenberg AFB, California, and the PMRF, Hawaii. These missions are conducted with the approval of the RTS Commander. A specific procedure is established to ensure that such approval is granted only when the safety of all proposed tests has been adequately addressed.

Range safety is accomplished by compliance with RTS regulations and use of established procedures and safety precautions to prevent injury to people and minimize damage to property. Range safety applies to preparation, testing and execution of RTS programs. Other range safety objectives are the successful completion of mission objectives.

All program operations must receive the approval of the Safety Office. This is accomplished by the user through presentation of the proposed program to the Safety Office. All safety analyses, SOPs, and other safety documentation applicable to those operations affecting RTS must be
Ground Safety

Ground safety is the protection of range personnel and the public from injury when conducting potentially hazardous operations and handling hazardous materials. Several of the islands are affected by building construction, the storage and assembly of explosives and rocket propellants, and the operation of heavy equipment.

Kwajalein Island is the center of RTS operations and has activities that include receiving fuels, propellants and explosives; maintaining aircraft vehicles and other equipment; providing electricity, water and waste disposal services; and conducting specialized testing activities. Kwajalein, Roi-Namur, Meck, Omelek, and Illeginni Islands are, or in the past have been, sites for assembling and launching missiles.

Missile launch programs at RTS typically consist of single or multi-staged solid propellant missiles with payloads that may contain liquid propellants. The solid rocket motors are composed of fuels and oxidizers in a rubber binding material (other chemical compounds are added to modify performance characteristics). While solid rocket motors are classified as explosives, most propellants do not detonate, but are extremely flammable. Payload vehicles have propulsion systems based on gaseous propellants such as helium or nitrogen, or liquid propellants such as monomethyl hydrazine and nitrogen tetroxide. Liquid fuels may be toxic, corrosive, and/or flammable.

Explosives are used at RTS for missile flight programs and for destruction of unexploded ordnance, fireworks, small arms rounds, and flares. Small amounts of explosives are used in missile launches for stage separation and flight termination systems, which destroy in-flight missiles that show abnormal flight characteristics. Explosives are stored on Kwajalein, Roi-Namur, and Meck. Solid rocket motors are stored on Kwajalein and Roi-Namur and moved to the other islands for a limited time before launches.

Launch facilities consist of structures used for the assembly and launch of missiles that contain experimental payloads. The primary buildings are missile assembly buildings, payload assembly buildings, launch control buildings and launch pads. These structures are spaced according to ESQD criteria defined in AR 385-64, "U.S. Army Explosives Safety Program," and other regulations. The buildings at launch areas are designed to protect personnel from explosive pressure and fragments. Launches on smaller islands may be done remotely, when building separation is insufficient to protect personnel. The number of personnel working at launch facilities is limited during missile assembly and other potentially hazardous operations.

The site plans of launch facilities are reviewed and approved by the DoD Explosives Safety Board before construction. This evaluation takes into account the separation between magazines, operations buildings, transportation routes and unrelated inhabited buildings. Waivers for building separation have been obtained for storage magazines adjacent to the Kwajalein and Roi-Namur airfields.
The ground safety plans for programs at RTS contain emergency procedures for response to potential accident scenarios. For example, the emergency procedures for a missile launch program include the response to misfire and hangfire conditions, an explosion or fire on the launch pad, and the impact of an errant missile flight.

Fire protection is provided by fire suppression systems in most operations buildings and by continuously staffed fire stations on Kwajalein, Roi-Namur, and Meck Islands.

** Missile Flight Safety **

Flight safety provides protection to RTS personnel, inhabitants of the Marshall Islands, and ships and aircraft operating in areas potentially affected by these missions. Specific procedures are required for the preparation and execution of missions involving aircraft, missile launches, and reentry payloads. These procedures include regulations, directives, and flight safety plans for individual missions.

The area affected by aircraft and missile operations varies according to the type of mission. Incoming reentry vehicle impacts may affect the Mid-Atoll Corridor or the BOA to the north and east of the atoll. Aircraft operations may affect an area of 289 kilometers (180 miles) around RTS. A larger area is affected by sounding rocket or ballistic missile launches from RTS with trajectories typically to the north-northeast, where the lowest number of inhabited islands are located.

The largest affected areas result from test flights involving the collision of a target missile with an interceptor missile launched from RTS. The collision debris footprint, or area where collision debris could fall, extends for hundreds of miles away from the designated intercept point.

Flight safety activities include the preparation of a flight safety plan that includes evaluating risks to inhabitants and property near the flight, calculating trajectory and debris areas and specifying range clearance and notification procedures.

Flight safety plans are developed for both launch missions and incoming reentry vehicles. Potential hazards exist at RTS when missiles are launched and when reentering payloads are targeted for areas near the islands. Reentry vehicles are typically launched from Vandenberg AFB in California, PMRF in Hawaii, or Wake.

Notification is made to inhabitants near the flight path, and international air and sea traffic in the caution area designated for specific missions. Warning messages are transmitted to appropriate authorities to clear caution areas of this traffic and to inform the public of impending missions. The warning messages contain information describing the time and area affected and safe alternate routes. RMI is informed in advance of launches and reentry payload missions.

In missions that involve the potential for reentry debris near inhabited islands, precautions are taken to protect personnel. In Mid-Atoll hazard areas, where an island has a high probability of impact by debris, personnel are evacuated. In caution areas, where the chance of debris impact is low, precautions may consist of evacuating or sheltering non mission essential personnel. Sheltering is required for reentry vehicle missions impacting the Mid-Atoll Corridor in
Kwajalein Atoll. The Mid-Atoll Corridor is declared a caution area when it contains a point of impact.

Instrumentation is used for range safety by tracking incoming reentry vehicles and terminating missile flights in order to prevent an impact on inhabited islands. The Kwajalein Range Safety System links the RTS radar system to a range safety center on Kwajalein. A missile and payload can be tracked during the entire flight by the range safety center. Missiles launched from RTS are equipped with flight termination systems that allow destruction of the missile if the flight deviates significantly from planned criteria or otherwise poses a threat to the public. For example, a flight would be terminated if the missile path intersects the Marshall Islands protection circle, an artificial boundary around inhabited atolls and islands.

**RTS Sensor Complex**

EMR emitted from RTS radars is a potential hazard to humans and a potential source of interference with other communications and sensing equipment. Radars and RF transmitters emit non-ionizing radiation. Communications emissions are generally of low frequency and low emitted power and pose minimal threat. Radar testing at RTS involves several powerful radar systems and requires safety measures to protect RTS personnel. Sources of EMR at RTS and the mechanisms used to ensure the safety of personnel and to prevent interference are described in the *Final Ground-Based Radar (GBR) Family of Radars Environmental Assessment and Finding of No Significant Impact* (U.S. Army Program Executive Office Missile Defense, 1993).

According to a U.S. Army Space and Missile Defense Command fact sheet, the RTS complex of radar, optical and telemetry sensor instrumentation includes:

- **Radar**—High-resolution radars provide precision metric, signature, and imaging for deep-space operations, satellite observations, strategic reentry missions, and multiple-intercept engagement tracking. RTS’s wide range of radar capability includes S-band, L-band, C-band, Ka-band, and W-band, as well as beacon tracking, passive skin tracking, and impact scoring.
- **Optics**—Precise optical metric data are collected on objects both inside and outside the atmosphere using large-aperture optics equipped with video, infrared, and film sensors. RTS’s optics capability includes 35/70-millimeter cameras with frame rates up to 2,500 frames per second and focal lengths to 1,219 centimeters (480 inches).
- **Telemetry**—Critical onboard missile information transmitted to the ground is collected with nine geographically dispersed telemetry antennas capable of receiving data at frequencies of 1,700 to 2,400 megahertz (MHz). State-of-the-art ground stations receive, record, and display up to 30 megabytes of mission data.

The RTS integrated command and control center provides technical range support with secure fiber optic network and offers the range user calibration, range timing, meteorology, flight/ground safety, logistics, and data reduction/analysis services.

There are currently 22 RF sources at RTS, including 11 radar systems and 11 communication transmitters. Kwajalein has seven major sources of microwave radiation; Roi-Namur has five
sources, four of which are the major radar systems at RTS. There are smaller radar systems on the mid-atoll islands of Legan and Gellinam.

RTS radars are typically operated at a minimum inclination of 2 degrees above horizontal, which allows a hazard free zone from ground surface to at least 5 meters (15 feet). In tests requiring radar beams to go below the horizon, safety procedures require exclusion from hazard zones. Radar systems have mechanical and software stops to prevent the main beam from being directed at the ground or in specified sectors where it may present a hazard. Radars also have the potential to interfere with aircraft instrumentation. More powerful radars, such as TRADEX, have computer-controlled interlocks to reduce power output in the direction of approaching aircraft.

The primary physical reaction to EMR exposure is cellular heating with symptoms such as eye damage as an early consequence. EMR hazard zones provide a safety factor 10 times greater than the Institute of Electrical and Electronics Engineers (IEEE) Maximum Permissible Exposure Limit (MPELs). Per IEEE Standard C95.1-1999, Standard for Safety Levels with Respect to Human Exposure to Radio Frequency Electromagnetic Fields, 3 kHz to 300 GHz, MPELs are capped at 5 milliwatts per square centimeter (mW/cm²) for frequencies greater than 1,500 MHz. General public exposure is typically limited to one-fifth of the occupational limits. These hazard zones are defined in Army guidance and regulations on microwave and RF safety (appendix B). For non-ionizing radiation, OSHA established a radiation protection guide (29 CFR 1910.97, Non-ionizing Radiation) for normal environmental conditions and for incident electromagnetic energy of frequencies from 10 MHz to 100 MHz. This radiation protection guide is 10 mW/cm², as averaged over any possible 1-hour period. DoD Instruction 6055.11, Protection of DoD Personnel from Exposure to Radiofrequency Radiation, established permissible exposure limits (PELs) for controlled and uncontrolled environments and for High Power Microwave narrow-band and Electromagnetic Pulse broad-band simulator systems.

Regional Safety
The Kwajalein Hospital is the primary health care facility for RTS. The approximate 16-bed hospital has a dental clinic and provides emergency treatment, surgical, obstetric, general medical and diagnostic services for the community and range personnel. One medical technician staffs a dispensary located on Roi-Namur. A first aid station on Meck is also staffed by a medical technician. The hospital, dispensary, and first aid station is contractor operated and staffed. Video consultations with Tripler Army Medical Center in Honolulu, Hawaii provide access to medical specialists for those patients requiring supplemental evaluation. Medical specialists such as optometrists schedule periodic visits to Kwajalein. Other health facilities in the RMI include a private clinic on Majuro and a public hospital on Ebeye.

3.3.6 UTILITIES—REAGAN TEST SITE

3.3.6.1 Region of Influence
The ROI includes areas of Kwajalein that may potentially be affected by the use of Kwajalein Lagoon for the SBX activities, as well as the potential construction of an environmentally controlled warehouse. This site has not been determined.
3.3.6.2 Affected Environment

Utilities at USAKA/RTS are operated to meet the needs of the resident population of approximately 2,500 people, including dependants. However, it must be noted that this figure varies depending on mission status and construction activity.

Energy

Kwajalein has one electrical power plant using engine generator sets that burn diesel fuel; the electricity is distributed by underground feeders. In 1993, there were three power plants (PP1, PP2, and PP1A), which had a combined capacity of 26,790 kW. Historical peak loads totaled 13,500 kW over different periods, or 50 percent of capacity (U.S. Army Space and Strategic Defense Command, 1993a). Power distribution is conventional, with underground high-voltage transmission lines and aboveground “user voltage” (110-220 volt alternating current) distribution lines. Generating capacities have not changed in several years. Currently, there are seven generators operating with a total output of 29,200 kW (U.S. Army Space and Missile Defense Command, 2002b). The power plant at Kwajalein is designated Power Plant 1A and 1B.

Power Plant 1A became operational in April 1991 and reached full plant production in June 1991. Power Plant 1A produced 58 percent of Kwajalein’s electrical requirements for June through December 1991 and was expected to produce a higher percentage of the island’s power in future years. Power Plant 1B went online in 1994 with four 4,400-kW units. Once Power Plant 1A and Power Plant 1B became functional, there was no longer a need for Power Plant 1 or Power Plant 2, so they were decommissioned.

Water

Kwajalein has a conventional package filter drinking water system for potable (drinkable) water production. Under normal conditions, Kwajalein’s potable water system can provide an adequate supply of fresh water. In 1993, the daily supply of 1.6 million liters (430,000 gallons) per day from rainwater treatments, and groundwater was more than sufficient to meet the average demand of 1.1 million liters (300,000 gallons) per day. A desalination facility was decommissioned in 2002.

The capacity of the system is 1,703,435 liters (450,000 gallons) per day. Upgrades are in progress to improve this system’s ability to meet USAKA/RTS environmental standards. These upgrades include the addition of reverse osmosis to units for control of total trihalomethanes and haloacetic acids. Drinking water quality is produced to meet the standards of the UES. Drinking water standards are essentially the same as EPA standards for public systems that serve a population of 10,000 people (U.S. Army Space and Missile Defense Command, 2001a).

Raw water is provided primarily by a rainwater catchment system along the runway. During dry seasons, additional water is provided by pumping the freshwater lens that forms an unconfined surficial aquifer beneath the island surface. Portable reverse osmosis water-purifying units are employed to remove organic contaminants from the lens well water. (U.S. Army Space and Missile Defense Command, 2002b)

Kwajalein has twelve 1-million-gallon (3.8-million-liter) reinforced concrete tanks for storage of rainwater collected from the catchments and lens wells. Rain water is pumped from storage to treatment in the package water treatment plant. The treated water receives pH adjustment and
chlorination before being stored in one of two covered concrete tanks. Nine of the 14 existing raw water storage tanks are covered.

**Wastewater**

The wastewater system for Kwajalein consists of a force main and gravity collection system, nine pump stations, a secondary wastewater treatment plant, and an outfall extending into the lagoon. The wastewater treatment plant is now approximately 20 years old. Plant flow for the period September 1992 through August 1993 averaged 1.4 million liters (382,000 gallons) for this period at approximately 560 liters (148 gallons) per capita per day. Wastewater is reclaimed by conventional secondary treatment followed by chemical (chlorine) disinfection. Reclaimed water is used for non-potable uses, including sanitation and irrigation. Excess water is discharged in accordance with the UES. Wastewater sludge is treated and composted per the UES for use as soil amendment for lawns, landscaping, and gardens (U.S. Army Space and Missile Defense Command, 2002b).

**Solid Waste**

Kwajalein Island generates approximately 20.3 to 30.5 metric tons (20 to 30 tons) of municipal solid waste per day. Green waste is collected and taken to a composting area. Food wastes are no longer disposed of in the ocean off Kwajalein. The compost mulch is used for landscaping and in a nursery. Municipal solid waste is incinerated at the incinerator facility. Ash and inert waste solids are buried at an adjacent landfill. Metals are shipped to Honolulu to be recycled (U.S. Army Space and Missile Defense Command, 2002b). Waste batteries are shipped off-island intact. Used oil is collected in 208.2-liter (55-gallon) drums and used for energy reclamation. Glass, concrete rubble, and similar materials are processed for reuse as construction (including shoreline protection) and fill material at USAKA.
3.4 PACIFIC MISSILE RANGE FACILITY

The existing environment at PMRF was described in the PMRF Enhanced Capability EIS (Pacific Missile Range Facility, Barking Sands, 1998) and the North Pacific Targets Program EA (U.S. Army Space and Missile Defense Command, 2001b). For the most part, those descriptions are still accurate and are not repeated in this document. Rather, for resources that may be affected by ETR activities at PMRF, the pertinent resource discussions are summarized, and any differences in existing environmental conditions, including new facilities or infrastructure, are noted. The more detailed discussion in the Final EA or EIS is incorporated by reference and will be made available for review by those who wish more information concerning the existing environment at PMRF.

The proposed ETR activities could have an effect on air quality, biological resources, hazardous materials and waste, health and safety, and socioeconomics at PMRF. These resource areas are summarized in the following sections.

Areas that are not expected be affected sufficiently at PMRF to warrant further discussion include airspace, cultural resources, geology and soils, land use, noise, transportation, utilities, visual and aesthetic resources, water resources, and environmental justice. The ongoing missile launches and use of transportable radars result in short term temporary impacts to airspace that are mitigated through coordination with the FAA. While many areas of PMRF have important historic resources, many of them relating to native Hawaiian culture, there are not expected to be any ground disturbing activities within areas where these resources are located. Activities proposed in the GMD ETR EIS would adhere to the 1999 Memorandum of Agreement between the U.S. Department of the Navy, PMRF, and the Hawaii State Historic Preservation Officer as shown in the PMRF Enhanced Capability EIS (Pacific Missile Range Facility, Barking Sands, 1998). While proposed target launch activities will result in minor soil contamination from rocket emissions in and around the designated Launch Hazard Area at KTF, it is not expected to create adverse effects beyond those previously analyzed in the PMRF Enhanced Capability EIS (Pacific Missile Range Facility, Barking Sands, 1998). Land use at PMRF and surrounding areas would not change. Utilization of adjacent lands would be consistent with existing land use agreements. The existing noise levels at PMRF would continue, including those associated with proposed missile launches. Noise generated during the launches would be anticipated to have minimal impact on off-base areas and would not affect the noise levels estimated in the current PMRF Air Installation Compatible Use Zone report. None of the noise levels outside of the Ground Hazard Area boundary for the proposed launch areas where non-essential personnel and the public are excluded would exceed either DoD or OSHA safety requirements. Personnel within the Ground Hazard Area wear hearing protection devices. Any increase in daily trips by support personnel, including any utilized to support mid-range telemetry functions, would be short term and small, utilizing existing transportation infrastructure. Shared vehicle and/or off-peak hour travel would further serve to minimize effects on transportation levels. The utilities infrastructure and water resources requirements for the proposed activities are included in the existing usage levels and are not expected to be adversely affected by the proposed activities. Although the visual resources on PMRF may be considered significant by some viewers, much of the area is already developed with the types of structures and activities that are being considered in the Proposed Action. Therefore, this section does not include further analysis of visual resources at PMRF. An Environmental Justice impact would be a long-term health, environmental, cultural, or economic effect that has a disproportionately high and adverse effect on a nearby minority or low-income population, rather than all nearby residents. No adverse long-term impacts have been identified at the proposed sites on PMRF. As such, there would be no disproportionately high and adverse
human health or environmental effects on the minority or low-income populations that may be present in the vicinity of those locations.

3.4.1 AIR QUALITY—PACIFIC MISSILE RANGE FACILITY

Appendix B includes a general description of air quality.

3.4.1.1 Region of Influence

For inert pollutants (all pollutants other than ozone and its precursors), the ROI is generally limited to an area extending no more than a few tens of miles downwind from the source.

The ROI for ozone may extend much further downwind than the ROI for inert pollutants; however, as the project area has no heavy industry and very few automobiles, tropospheric ozone and its precursors are not of concern. Consequently, for the air quality analysis, the ROI for project operational activities is the existing airshed surrounding the various sites, which encompasses the Mana Plain, including the PMRF/Main Base and Ground Hazard Area restrictive easements.

3.4.1.2 Affected Environment

Climate

PMRF, which is located just south of the Tropic of Cancer, has a mild and semitropical climate with scattered clouds and generally light and variable trade winds from the northeast.

Regional Air Quality

The only sampling station on Kauai is located in Lihue, and monitors for PM-10. The State of Hawaii is in attainment of the NAAQS established for carbon monoxide, nitrogen dioxide, sulfur dioxide, particulate matter, ozone, and lead (40 CFR 81.312 and 52.631(b)).

The major source of air pollution emissions external to, and not associated with, PMRF/Main Base is the seasonal burning of the cane fields east of the base. This burning produces periods of elevated smoke and ash. In addition, the smoke temporarily degrades visibility over an extended area.

Existing Emissions Sources

The main pollution sources at PMRF are diesel-fuel powered generators, aircraft, and rocket launches. PMRF was issued a Title V Covered Source Permit for five diesel generators, which covers all significant stationary emission sources on PMRF. Aircraft emissions and missile exhaust emissions are both considered mobile sources and are thus exempt from permitting requirements. (Pacific Missile Range Facility, Barking Sands, 1998) Table 3.4.1-1 lists the estimated exhaust products from typical launch vehicles at PMRF as presented in the PMRF Enhanced Capability EIS. (Pacific Missile Range Facility, Barking Sands, 1998) No adverse air quality impacts were anticipated from current launches.
Table 3.4.1-1: Estimated Emissions of Typical Missile Launches at PMRF

(2) Talos/Zest emissions based on commercial version of TSCREEN/PUFF model at 3,000 meters (9,840 feet)
(3) Strategic Target System used Rocket Exhaust Effluent Dispersion Model to model Hydrogen Chloride
(4) At 190 meters (623 feet)
(5) Value is a 1-hour TWA. Due to near-instantaneous nature of emissions, 8-hour TWA would be lower
(6) At 3,000 meters (9,840 feet)

TLV = Threshold Limit Value
TWA = Time-weighted Average

3.4.2 BIOLOGICAL RESOURCES—PACIFIC MISSILE RANGE FACILITY

Appendix B includes a definition of biological resources and the main regulations and laws that govern their protection.

3.4.2.1 Region of Influence

The ROI includes areas on PMRF that may be affected by target launches from existing launch sites and the use of existing sensors.

3.4.2.2 Affected Environment

Vegetation

The vegetation on PMRF/Main Base is composed of two principal habitat types: non-native ruderal vegetation and kiawe/koa haole scrub. Within PMRF/Main Base and the KTF area of the complex, ruderal vegetation is present where man has disturbed the natural vegetation, and much of this vegetation is mowed on a regular basis. The vegetation adjacent to PMRF/Main Base in the Ground Hazard Area is dominated by sugar cane, ruderal vegetation, and wetlands associated with agricultural ponds and drains. Kiawe/koa haole scrub and ruderal vegetation are the dominant vegetation in the undeveloped portions of the PMRF/Main Base ROI. In the south-central part of PMRF/Main Base, mosaic-like patches of vegetation dominated by the indigenous wedge-leaf hop bush are present on a sandy substrate. Coastal dune vegetation covers much of the dunes north of KTF, and a well-developed native strand community exists along the shoreline.

Vegetation at Makaha Ridge is dominated by introduced non-native species. Well-maintained grassy lawns and landscape plantings are located around the existing buildings. A few shrubs of the native false sandalwood or naio and the introduced lantana occur along the makai (coastal) edge of the Makaha Ridge complex. (Pacific Missile Range Facility, 2000)
Threatened and Endangered Plant Species
Table 3.4.2-1 lists threatened and endangered species that could potentially be located within the ROI.

</tbody>
</table>

Two federally listed plant species have been observed north of PMRF. Ohai (Sesbania tomentosa), a spreading shrub, is a federally endangered species that has been observed in the sand dunes to the north of the KTF launch complex and in Polihale State Park and could potentially occur on PMRF/Main Base. Lau‘ehu (Panicum niihauense), a federally endangered species of rare grass, has been observed near Queens Pond north of PMRF/Main Base.
The dwarf iliau (*Wilkesia hobyi*), an endangered member of the daisy or sunflower family, is found on rocky outcrops of the cliff overlooking Makaha Valley to the north of the tracking station on Makaha Ridge (Department of the Navy, Pacific Missile Range Facility, Hawaii, 2001).

**Wildlife**

Forty species of birds have been identified at PMRF/Main Base, including non-native and migratory birds and species endemic to Hawaii. The pueo (*Asio flammeus sandwichensis*) (Hawaiian short-eared owl) is a state listed endangered species. This owl is the only endemic terrestrial bird species that occurs in the region. Non-native bird species on Kauai are usually common field and urban birds such as the ring-necked pheasant. Several species of migratory waterfowl may be present during some portion of the year. The Laysan albatross, a migratory bird protected under the Migratory Bird Treaty Act, uses ruderal vegetation areas for courtship and nesting. PMRF has an ongoing feral dog-trapping program to protect the albatross as well as the wedge-tail shearwater and other birds on base. However, the Laysan albatross is being discouraged from nesting at PMRF/Main Base to prevent interaction between the species and aircraft using the runway. Albatross on the airfield are tagged and released on the north portion of the base or returnees are relocated to Kilauea National Wildlife Refuge in order to prevent bird/aircraft strikes. This action is being accomplished under a USFWS permit. (Pacific Missile Range Facility, Barking Sands, 1998; U.S. Army Space and Missile Defense Command, 2001b)

Feral dogs and cats occur in the region and prey on native and introduced species of birds. Rodents including the Polynesian black rat, Norway or brown rat, and the house mouse are also known to occur in the region. (Pacific Missile Range Facility, Barking Sands, 1998; U.S. Army Space and Missile Defense Command, 2001b)

Three endemic birds, the white-tailed tropicbird, the Pacific golden plover, and the common amakahi, have been observed at Makaha Ridge. Introduced birds commonly found in this area of Kauai include the spotted dove, zebra dove, and the common myna. In addition, two native species that may occur in the area are the short-eared owl and the Hawaiian honeycreeper (*'i'iwi*). It is likely that mice or rats inhabit the Makaha Ridge area. Feral goats have been seen in this general area. (Pacific Missile Range Facility, 2000)

**Essential Fish Habitat**

Essential Fish Habitat occurs and is incorporated within Kauai’s Exclusive Economic Zone, the 322-kilometer (200-mile) limit around the island. Essential Fish Habitat for adult and juvenile bottomfish includes the water column and all bottom habitat extending from the shoreline to a depth of 400 meters (219 fathoms), which encompasses important steep drop-offs and high relief habitats. Shallow-water (0 to 100 meters [0 to 55 fathoms]) bottomfish species include uku, thicklip trevallys, groupers, emperors, amberjack, and taape. Deep-water (100 to 400 meters [55 to 219 fathoms]) species include ehu, onaga, opapaka, gindai, hapupuu, and lehi. (Western Pacific Fishery Management Council, 1998)

Pelagic habitat areas of particular concern are designated as the water column down to 1,000 meters (3,280 feet) from the shoreline to the Exclusive Economic Zone that lies above all seamounts and banks shallower than 2,000 meters (1,100 fathoms). Marketable pelagic species include striped marlin, bluefin tuna, swordfish, albacore, mackerel, skipjack, sailfish, kawakawa, and various sharks. (Western Pacific Fishery Management Council, 1998)
Banks with summits less than 30 meters (98 feet) have been designated as habitat areas of particular concern for crustaceans. Crustacean species include spiny lobster, slipper lobsters, and Kona crabs. (Western Pacific Fishery Management Council, 1998)

*Threatened and Endangered Wildlife Species*

Table 3.4.2-1 lists threatened and endangered species that could potentially be located within the ROI.

Six species of birds that are listed as federally threatened or endangered are potentially present or confirmed in the PMRF area. Kauai provides the majority of the nesting habitat for the federally threatened Newell’s Townsend’s shearwater (*Puffinus auricularis newelli*). The Newell’s shearwater nests from April to November in the interior mountains of Kauai. Nestlings leave the nesting grounds at night in October and November and head for the open ocean. They may become temporarily blinded by lights when flying near brightly lit urban areas or street lights and some may collide with trees, utility lines and light poles, buildings, and automobiles. The most critical period for these collisions is a week before and a week after the new moon in October and November.

The Hawaiian dark-rumped petrel (*Pterodroma phaeopygia sandwichensis*), which is listed as federally endangered, may traverse the area from its nesting grounds to the sea. Fledging of the dark-rumped petrel occurs in October, slightly earlier than that of the Newell’s shearwater.

The Hawaiian (American) coot (*Fulica americana alai*), Hawaiian black-necked stilt (*Himantopus mexicanus knudseni*), Hawaiian common moorhen (*Gallinula chloropus sandvicensis*), and Hawaiian duck (*Anas wyvilliana*) are federal and state endangered birds that have been observed in the drainage ditches and ponds on PMRF.

The federal and state endangered Hawaiian goose (*Nesochen sandvicensis*), or *ne ne*, occurs as a breeding population within the Makaha Ridge facility (Pacific Missile Range Facility, 2000).

The Hawaiian hoary bat (*Lasiurus cinereus semotus*) is listed as a federal and state endangered species. While it has not been recorded as flying over PMRF, it is known to feed offshore and has been observed at the Polihale State Park north of the base. It is likely that the bat also flies over PMRF.

Three marine wildlife species listed as federal and state threatened or endangered commonly occur in the area. The endangered Hawaiian monk seal (*Monachus schauinslandi*) is an indigenous mammal that has been observed at PMRF. The first Hawaiian monk seal birth observed on a Kauai beach since 1993 occurred on PMRF in 1999 on the beach adjacent to the runway (Pacific Missile Range Facility, 1999). Only four other Hawaiian monk seal births had been recorded on Kauai since 1961 (Navy Environmental News, 1999). The fact that humans frequent all beaches on PMRF may generally discourage use by monk seals.

The federal threatened and state endangered green sea turtle (*Chelonia mydas*) basks and nests on PMRF adjacent to the Nohili Ditch (Pacific Missile Range Facility, 1999; Pacific Missile Range Facility, 2001). Ninety percent of the Hawaiian population of the green sea turtle returns to French Frigate Shoals to breed (University of Hawaii, 2002).
The federal and state endangered migratory humpback whale is known to use the channel between Kauai and Niihau. Approximately two-thirds of the North Pacific population of humpback whales winter in Hawaii.

**Environmentally Sensitive Habitat**

**Wetlands**

Wetlands are associated with the Mana base pond, Kawaiele wildlife sanctuaries (a State Waterbird Refuge for Hawaii’s four endangered waterbird species, created at Mana during a sand removal program), and agricultural drains (Nohili and Kawaiele ditches) within PMRF/Main Base.

**Hawaiian Islands Humpback Whale National Marine Sanctuary**

The Hawaiian Islands Humpback Whale National Marine Sanctuary was created by Congress in 1992 (figure 3.4.2-1). A small portion of the sanctuary lies within the ROI. Humpback whales are endangered marine mammals and are therefore protected under provisions of the Endangered Species Act and the Marine Mammal Protection Act wherever they are found. Humpbacks are seen in the winter months in the shallow waters surrounding the Hawaiian Islands where they congregate to mate and calve. The humpback population is growing by an average of 7 percent annually. That means their numbers, which stand at about 5,000, would double in approximately 13 years. The whales travel more than 5,633 kilometers (3,500 miles) from Alaska to Hawaii’s warm waters to mate, give birth, and care for their calves. The estimated 5,000 whales traverse more than a half-million square kilometers (quarter-million square miles) of ocean surrounding Hawaii. The first whales of the season usually arrive around October, with the greatest number seen around Hawaii between 1 December and 15 May. (Star Bulletin, 2002)

**Submerged Barrier Reef Offshore of PMRF**

A submerged barrier reef, roughly 13 kilometers (8 miles) long, lies offshore of PMRF. Coral density is low and is dominated by lobe coral (*Porites lobata*) and small stands of arborescent (branched or tree shaped) corals.

**Northwestern Hawaiian Islands Coral Reef Ecosystem Reserve**

The Northwestern Hawaiian Islands Coral Reef Ecosystem Reserve is discussed in the BOA, section 3.11.

**Critical Habitat**

Critical habitat is the term used in the Endangered Species Act to define those areas of habitat that are known to be essential for an endangered or threatened species to recover and that require special management protection. A proposed rule to designate critical habitat for 76 listed plant species on the islands of Kauai and Niihau was published in the Federal Register in November 2000 (Federal Register, 2000b). This proposed rule included land in the northwestern end of PMRF near Polihale Park as critical habitat for the endangered ohai and lau‘ehe‘u. In January 2002, the USFWS proposed critical habitat for additional plant species on Kauai and

Niihau, revising the total number of plants to 83, which includes additional land in the southern portion of PMRF for protection of lau’ehu. (U.S. Fish and Wildlife Service, Pacific Region, 2002a; Federal Register, 2002) The USFWS reevaluated the dune habitat on PMRF and the habitat on Navy land at Makaha Ridge and determined that these lands were not essential for the conservation of ohai or dwarf iliau. However, the USFWS has determined that land on PMRF adjacent to Polihale State Park and dune areas along the southern portion of the range contain primary constituents necessary for the recovery of lau’ehu because not enough areas exist outside of PMRF. If the Navy revises its Integrated Natural Resources Management Plan to address the maintenance and improvement and long-term conservation of the lau’ehu, the USFWS will reassess critical habitat boundaries. (Federal Register, 2003)

3.4.3 HAZARDOUS MATERIALS AND HAZARDOUS WASTE—PACIFIC MISSILE RANGE FACILITY

Appendix B includes a general definition of hazardous materials and hazardous waste and a brief summary of regulations and laws.

3.4.3.1 Region of Influence

The ROI for potential impacts related to hazardous materials/wastes would be limited to areas of the PMRF to be used for launch preparation, launch, and post-launch activities, and in areas where hazardous materials are stored and handled.

3.4.3.2 Affected Environment

Hazardous Materials and Hazardous Waste Management

Hazardous Materials Management

PMRF manages hazardous materials through the U.S. Navy’s Consolidated Hazardous Materials Reutilization and Inventory Management Program (CHRIMP). CHRIMP mandates procedures to control, track, and reduce the variety and quantities of hazardous materials in use at facilities. The CHRIMP concept established Hazardous Materials Minimization Centers as the inventory controllers for U.S. Navy facilities. All departments, tenant commands, and work centers must order hazardous materials from the Hazardous Materials Minimization Centers, where all such transactions are recorded and tracked. The exception to this is KTF, which obtains its hazardous materials through Department of Energy channels. Hazardous materials on PMRF are managed by the operations and maintenance contractor through CHRIMP. Hazardous materials managed through the CHRIMP program other than fuels are stored in Building 338. Typical materials used on PMRF/Main Base and stored at Building 338 include cleaning agents, solvents, and lubricating oils. (Pacific Missile Range Facility, Barking Sands, 1998)

PMRF has management plans for oil and hazardous materials outlined in the PMRF Spill Prevention Control and Countermeasures Plan and the Installation Spill Contingency Plan, both of which also regulate tenant organizations and PMRF associated sites. (Pacific Missile Range Facility, Barking Sands, 1998) Specifically, sites included are KTF, Makaha Ridge, Kokee, Kamokala Magazines, and Port Allen.
PMRF has developed programs to comply with the requirements of the Superfund Amendments and Reauthorization Act Title III and Emergency Planning and Community Right-to-Know Act. This effort has included submission to the state and local emergency planning committees of annual Tier II forms, which are an updated inventory of chemicals or extremely hazardous substances in excess of threshold limits. These chemicals at PMRF include jet fuel, diesel fuel, propane, gasoline, aqueous fire fighting foam, chlorine, used oil, paint/oils, and paint.

**Hazardous Waste Management**

PMRF/Main Base is a large-quantity hazardous waste generator with an EPA number. Hazardous waste on PMRF is not stored beyond the 90-day collection period. In 1996, PMRF/Main Base generated 40,214 kilograms (88,654 pounds) of hazardous waste, which is a significant reduction in the amount of hazardous waste generated when compared to the 88,800 kilograms (195,766 pounds) generated in 1990.

PMRF/Main Base has two accumulation points on base for hazardous wastes: Building 392 and Building 419. Building 392 accumulates all base waste except for otto (torpedo) fuel, a liquid monopropellant. Building 419 is the torpedo repair shop. At present, both buildings are not used at their maximum hazardous waste storage capacity. KTF has one accumulation point.

Makaha Ridge and Kokee generate only used oil, which is recycled. Port Allen generates used oil, paint wastes, and oily bilge water. The oily bilge water is processed through an oil/water separator and then is fed into the nearby sewage treatment plant. (Pacific Missile Range Facility, Barking Sands, 1998)

Under state regulations oil is not regulated as a hazardous waste, but is a hazardous substance subject to notification. (Pacific Missile Range Facility, Barking Sands, 1998) PMRF outlines management and disposal procedures for used oils and fuels in the Hazardous Waste Management Plan. Additionally, degraded jet fuel is used in crash-fire training exercises.

The majority of wastes are collected and containerized at PMRF/Main Base for direct offsite disposal through the Defense Reutilization and Marketing Office (DRMO) at Pearl Harbor within 90 days. (Pacific Missile Range Facility, Barking Sands, 1998) The DRMO provides for the transportation and disposal of the wastes to the final disposal facility. (Pacific Missile Range Facility, Barking Sands, 1998)

KTF on PMRF/Main Base is a small-quantity generator and has an EPA identification number. (U.S. Army Program Executive Office, 1995) KTF has not generated enough hazardous waste for disposal since becoming a small quantity generator in 1994. (Pacific Missile Range Facility, Barking Sands, 1998)

**Pollution Prevention/Recycling/Waste Minimization**

PMRF has a pollution prevention plan in place for the Main Base and all sites on Kauai, which was updated in February 1996 and follows CHRIMP procedures for controlling, tracking and reducing hazardous materials use and waste generation. (Pacific Missile Range Facility, Barking Sands, 1998) In regards to hazardous waste elimination programs, PMRF/Main Base currently has three in place. These involve the recycling of toner cartridges, mercury from mercury lamps, and acid/lead batteries. (Pacific Missile Range Facility, Barking Sands, 1998)
In calendar year 1996, 624 kilograms (1,376 pounds) of fluorescent tubes containing mercury were recycled, as well as 208 kilograms (458 pounds) of acid/lead batteries. (Pacific Missile Range Facility, Barking Sands, 1998) Additionally, all spent toner cartridges were sent to the manufacturer for recycling.

**Installation Restoration Program**

PMRF/Main Base has 16 IRP sites. The two fire fighting training pits, the battery acid disposal pit, and the torpedo post run facility require no further action based on the results of past investigations and approval by the State of Hawaii, Department of Health.

Three former oil change pits and a battery acid neutralization unit are currently being investigated. Three landfills, a tanker truck pod facility, former missile (Regulus) defueling pit, and former oil/fuel pipelines are scheduled to be investigated.

Investigation at a reclamite asphalt rejuvenator burial area and various transformer sites (four each) have been completed and are waiting Department of Health concurrence for no further action. (Miyashiro, 2002)

**Underground and Aboveground Storage Tanks**

PMRF/Main Base has nine 189,270-liter (50,000-gallon) USTs and ten smaller USTs containing petroleum products. All USTs are equipped with a vapor detection system. The tanks were tested approximately 5 years ago, with no leaks detected. (Pacific Missile Range Facility, Barking Sands, 1998) Eight of the smaller USTs are 757-liter (200-gallon), double-walled, fiberglass-reinforced plastic.

**Asbestos, Lead-Based Paint, and Polychlorinated Biphenyls**

PMRF manages asbestos in accordance with the base asbestos management plan. Prior to any construction projects, areas to be disturbed are surveyed for asbestos, and any asbestos is removed, before disturbance, by a certified asbestos contractor.

The handling of hazardous materials and the potential generation and disposal of hazardous wastes follow ongoing, standard, and applicable regulations and procedures at PMRF.

All facilities associated with PMRF follow its lead-based paint management plan. The exception is KTF, which follows Department of Energy plans for the removal of lead-based paint wastes. Components containing PCBs that become waste are labeled according to the Toxic Substances Control Act, 40 CFR 761, requirements for shipping, and are disposed of through the DRMO or a contractor within 1 year of the waste’s initial storage.

**Liquid Fuels and Other Toxic Fuels**

PMRF uses gasoline and diesel fuels to power range trucks and equipment. Aircraft at PMRF utilize jet fuel, JP-10 and Jet-A. Jet-A and JP-10 fuels are available at the fuel farm near the airfield, and are delivered to the flight line in refuelers.
3.4.4 HEALTH AND SAFETY—PACIFIC MISSILE RANGE FACILITY

Appendix B includes a general description of health and safety.

3.4.4.1 Region of Influence

The ROI for potential impact related to the health and safety of workers is limited to work areas associated with transportation of missile components, missile storage and handling areas, missile launch, post-launch activities and radiation hazard areas. The population of concern for the Proposed Action would include the approximate 870 employed at PMRF, but would predominantly encompass the contractor, military, and government civilian personnel directly involved with target launch and launch support operations.

The ROI for potential impact related to public health and safety includes the areas of Kauai County and the island of Kauai affected by preflight transport of missile components, missile launch and missile flight. These areas include the PMRF overwater training areas. The population of concern for the Proposed Action consists of visitors to Kauai and the approximate 56,539 people living in Kauai County (U.S. Census Bureau, 2001).

3.4.4.2 Affected Environment

Range Safety

The U.S. Navy takes every reasonable precaution during the planning and execution of the operations, training exercises, and test and development activities to prevent injury to human life or property. In addition to explosive, physical impact, and electromagnetic hazards, potential hazards from chemical contamination, ionizing and non-ionizing radiation, radioactive materials, and lasers are studied by NAWCWD. (Pacific Missile Range Facility, Barking Sands, 1998)

Range Control is in charge of surveillance, clearance, and real-time range safety. Range Safety Approval and Range Safety Operation Plan documents are required for all weapons systems using PMRF. PMRF sets requirements for minimally acceptable risk criteria to occupational and non-occupational personnel, test facilities, and non-military assets during range operations. The NAWCWD, Point Mugu, is responsible for establishing Ground Hazard Areas and Launch Hazard Areas over water beyond which no debris from early flight termination is expected to fall. Hazard areas are determined by size and flight characteristics of the missile, as well as individual flight profiles of each flight test. Data processed by ground-based or onboard missile computer systems may be used to recognize malfunctions and terminate missile flight. Before an operation is allowed to proceed, the range is determined cleared using input from ship sensors, visual surveillance from aircraft and range safety boats, radar data, and acoustic information. Other safety areas under PMRF’s control include radars, explosives, airspace. All range users must: (1) provide a list of project materials, items, or test conditions that could present hazards to personnel or material through toxicity, combustion, blast, acoustics, fragmentation, EMR, radioactivity, ionization, or other means; (2) describe radiation, toxic, explosive, or ionization problems that could accumulate as a result of their tests; (3) provide warhead information (if any), aerodynamic and flight control information, and destruct system information and parameters; (4) submit plans, specifications, and procedural or functional steps for operations involving explosives to conform to criteria in the NAWCWD instruction; and (5) provide complete operational specifications of any laser to be used and a detailed description of its planned use. (Pacific Missile Range Facility, Barking Sands, 1998)
Missile Flight Analysis

PMRF conducts missile flight safety, which takes into account potential hazards from chemical contamination, ionizing and non-ionizing radiation, radioactive materials, and lasers in accordance with NAWCWD Instruction 5100.2. This includes analysis of missile performance capabilities and limitations, of hazards inherent in missile operations and destruct systems, and of the electronic characteristics of missiles and instrumentation. It also includes computation and review of missile trajectories, launch azimuths, and hazard area dimensions, review and approval of destruct systems proposals, and preparation of the Range Safety Approval and Range Safety Operational Plans required of all programs at PMRF. These plans are prepared by the NAWCWD, Point Mugu, for each program and must be in place before project initiation.

Ground Safety

The Range Control Officer using PMRF assets is solely responsible for determining range status and setting RED (no firing) and GREEN (range is clear and support units are ready to begin the event) range firing conditions. The Range Safety Approval and the Range Safety Operation Plan documents are required for all weapons systems using PMRF (Pacific Missile Range Facility, Barking Sands, 1998). PMRF uses RCC 321-02, Common Risk Criteria for National Test Ranges. RCC 321-02 sets requirements for minimally-acceptable risk criteria to occupational and non-occupational personnel, test facilities, and non-military assets during range operations. Under RCC 321-02, individuals of the general public shall not be exposed to a probability of fatality greater than 1 in 10 million for any single mission and 1 in 1 million on an annual basis. (Range Commanders Council, Range Safety Group, 2002)

Figure 3.4.4-1 shows the PMRF health and safety areas including the Ground Hazard Areas associated with missile launch activities at PMRF. These Ground Hazard Areas consist of Vandals at 1,829 meters (6,000 feet), Strategic Target Systems at a modified 3,048 meters (10,000 feet), and smaller 762-meter (2,500-foot) and 914-meter (3,000-foot) areas used for rail launch rockets.

To ensure the protection of all persons and property, safety procedures have been established and implemented for the Ground Hazard Areas. These SOPs include establishing road control points and clearing the area using vehicles and helicopters (if necessary). The road control points are established 3 hours before launch to allow security forces to monitor traffic as it passes through the Ground Hazard Area. At 20 minutes before launch, the area is determined to be clear of the public to ensure that, in the unlikely event of early flight termination, no injuries or damage to persons or property would occur. After the Range Safety Officer declares the area safe, the security force gives the all-clear signal, and the public is allowed to reenter the area. (Pacific Missile Range Facility, Barking Sands, 1998) No inhabited structures are located within the off-base sections of the Ground Hazard Area. To further minimize the potential for launch associated hazards, PMRF has a Missile Accident Emergency Team assembled for all launches from KTF and on-call status for PMRF launches in accordance with PMRF Instruction 5100.1F.

**Ordnance Management and Safety**

Ordnance safety includes procedures to prevent premature, unintentional, or unauthorized detonation of ordnance. Any program using a new type of ordnance device for which proven safety procedures have not been established requires an Explosive Safety Approval before the ordnance is allowed on PMRF or used on a test range. This approval involves a detailed analysis of the explosives and of the proposed operations, procedures, and facilities for surveillance and control, an adequacy analysis of movement and control procedures, and a design review of the facilities where the ordnance items will be handled.

Ordnance management procedures are found in PMRF Instruction (PMRFINST) 8020.5, *Explosive Safety Criteria for Range Users Ordnance Operations*. The Range Control Branch of the Range Programs Division is responsible for: (1) detailed analysis of all proposals concerning missiles or explosives and their proposed operation on the range; (2) establishing procedures for surveillance and control of traffic within and entering hazard areas; (3) reviewing the design of facilities in which ordnance items are to be handled to ensure that safety protection meets the requirements of Naval Sea System Command Publication (NAVSEAOP) -5, *Ammunition and Explosives Ashore, Safety Regulations for Handling, Storing, Production, Renovation, and Shipping*, Chapter 4; (4) training, certifying, and providing Launch Control Officers, Safety Monitors, and Ordnance personnel for operations involving explosive ordnance; (5) assuming responsibility for the control of all emergency facilities, equipment, and personnel required in the event of a hazardous situation from a missile inadvertently impacting on a land area; (6) providing positive control of the ordering, receipt, issue, transport, and storage of all ordnance items; and (7) ensuring that only properly certified handling personnel are employed in any handling of ordnance.

Ordnance is delivered to PMRF/Main Base by aircraft to the on-base airfield and by ship to Nawiliwili Bay, then over land by truck transport along Highway 50 to the base. The barges carrying explosives are met at Nawiliwili Harbor by trained ordnance personnel and special vehicles for transit to and delivery at PMRF. All ordnance is transported in accordance with DOT regulations. Ordnance is stored in caves at the Kamokala Magazine area, except for the Strategic Target System, which is stored in a specially constructed facility on KTF. (Pacific Missile Range Facility, Barking Sands, 1998) No mishaps involving the use or handling of ordnance have occurred at PMRF.

PMRF/Main Base has defined ESQD arcs. The arcs are generated by launch pads, the Kamokala Magazine ordnance storage area, the Interim Ordnance Handling Pad, and the Missile Assembly/Test Buildings 573 and 685. Only the ESQD arcs generated by the Interim Ordnance Handling Pad and Building 573 are covered by a waiver or exemption. The Kokole Point Department of Energy launch site can accommodate a 381-meter (1,250-foot) ESQD arc.

A 381-meter (1,250-foot) ESQD Red Label Area, to handle incoming and outgoing ordnance items, is centered on the airfield taxiway, 381 meters (1,250 feet) from Building 412 (see figure 3.4.4-1). A soft pad in the Red Label recovery area is used by helicopters for setting down targets and weapons recovered from the range. The 244-meter (800-foot) ESQD surrounding the soft pad falls totally within the Red Label ESQD area. (Pacific Missile Range Facility, Barking Sands, 1998)
Ocean Area Clearance

Range Safety officials ensure operational safety for projectiles, targets, missiles, and other hazardous operations into PMRF operational areas. The operational areas consist of two Warning Areas (W-186 and W-188) and one Restricted Area (R-3101) under the local control of PMRF. The Warning Areas are in international waters and are not restricted; however, the surface area of the Warning Areas is listed as “HOT” (actively in use) 24 hours a day. For special operations, multi-participant or hazardous weekend firings, PMRF publishes dedicated warning NOTMARs and NOTAMs 1 week before hazardous operations. In addition, a 24-hour recorded message is updated daily by Range Operations to inform the public when and where hazardous operations will take place.

The range safety clearance procedures at PMRF are some of the most rigorous because of the extra sensors available. Before an operation is allowed to proceed, the range is determined cleared using inputs from ship sensors, visual surveillance of the range from aircraft and range safety boats, radar data, and acoustic information from a comprehensive system of sensors and surveillance from shore.

Transportation Safety

PMRF transports ordnance (e.g., missiles) by truck from Nawiliwili Bay to PMRF along Highway 50. The barges carrying explosives are met at Nawiliwili Bay by trained ordnance personnel and special vehicles for transit to and delivery at PMRF. All ordnance is transported in accordance with DOT regulations. In addition, PMRF has established PMRFINST 8023.G, which covers the handling and transportation of ammunition, explosives, and hazardous materials on the facility.

In addition, liquid fuels (e.g., nitrogen tetroxide and unsymmetrical dimethylhydrazine) are transported to KTF. These fuels are shipped to the site by truck, aircraft or barge, which do not affect transportation routes on the island of Kauai. Transportation of these materials is conducted in accordance with DOT regulations and specific safety procedures developed for the location. (Pacific Missile Range Facility, Barking Sands, 1998)

Range Control and the FAA are in direct communication in real time to ensure the safety of all aircraft using the airways and the Warning Areas. Within the Special Use Airspace, military activities in Warning Areas W-186 and W-188 are under PMRF control. Warning Areas W-189, W-187, and W-190 are scheduled through the Fleet Area Control and Surveillance Facility.

The Warning Areas are located in international airspace. Because they are in international airspace, the procedures of the ICAO are followed. The FAA acts as the U.S. agent for aeronautical information to the ICAO, and air traffic in the ROI is managed by the Honolulu ARTCC.

Fire and Crash Safety

The U.S. Navy has developed standards that dictate the amount of fire/crash equipment and staffing that must be present based on the number and types of aircraft stationed on base, and the types and total square footage of base structures and housing. The PMRF fire department meets these standards by maintaining three P-19 crash trucks (two primary and one backup) with both water and foam delivery capacities. For structural fires, the fire department maintains
two combinations of structural fire trucks (one primary and one backup), and one brush fire truck as required by U.S. Navy standards for an installation the size of PMRF. One centrally located facility houses the equipment for both the flightline and the structure fire protection needs. The positioning of this facility also meets the U.S. Navy time and distance requirements for facility response.

In addition to fire equipment, PMRF has two ambulances and Emergency Medical Technician available 24 hours a day, 7 days a week.

3.4.5 SOCIOECONOMICS—PACIFIC MISSILE RANGE FACILITY

Appendix B includes a general definition of socioeconomics.

3.4.5.1 Region of Influence

The ROI for socioeconomics is defined as the island of Kauai, Hawaii. The Proposed Action site is situated on the western side of the island, and the primary areas of analysis will concern both the community situated adjacent to PMRF, Kekaha, and other main population centers on the island such as Kapaa and Lihue.

3.4.5.2 Affected Environment

Kauai is the fourth-largest Hawaiian island, covering 1,424 square kilometers (550 square miles), and northernmost in the chain. The county seat, Lihue, is the island’s commercial and transportation center. Other population centers include Kapaa, Kalaheo, and Kekaha, the community closest to the Proposed Action. Most of the island’s population lives in towns close to the coast or in the valleys a few miles inland. The island is characterized by both tourism and visitor related development and a certain extent of agricultural production. In 1992, the island was physically and economically decimated by Hurricane Iniki. It has taken almost 10 years to recover from the impacts of the hurricane.

Population and Housing

The population of Kauai County numbered 58,463 people as of 2000, having increased from 51,000 people in 1990 (14.2 percent) (U.S. Census Bureau, 2001). Kauai is the least populous of the major Hawaiian Islands representing, as of 2000, only 4.82 percent of the population of the state (1,211,537 people). The nearest county in size, Maui, had more than twice the number of inhabitants as Kauai as of 2000. Kauai has also exhibited the slowest growth rate of all the neighbor islands, remaining considerably behind the growth rates of Maui (27.6 percent) and Hawaii County (23.6 percent). However, Kauai did exceed the growth rate of the state by 5.0 percent (U.S. Census Bureau, 2001).

Prior to Hurricane Iniki striking the island in 1992, Kauai’s population had been projected to grow from approximately 52,000 (in 1990) to 65,000 by the year 2000. It was estimated in 1993 (Pacific Missile Range Facility, Barking Sands, 1998) that 8,000 to 10,000 of Kauai’s population had emigrated to flee the effects of the hurricane. The latest data shows that the population of Kauai is growing once more, albeit at a markedly slower rate that what was once projected.
As of 2000, there were an estimated 25,331 housing units within Kauai, of which 2,339 housing units were located within Lihue, 3,632 in Kapaa, and 1,162 in Kekaha. In addition, the U.S. Bureau of the Census reported that vacancy rates of rental housing on Kauai averaged 6.1 percent, compared with vacancy rates of 8.1 percent, 4.6 percent, and 6.0 percent, for Lihue, Kapaa and Kekaha respectively.

Visitor serving accommodations are numerous on Kauai, with many different sized hotels and motels. Kauai has approximately 7,200 rooms or 10 percent of the total 72,204 available visitor rooms in the state (eHawaiiGov, 2002).

Income and Employment
The U.S. Bureau of the Census reported that the per capita income in Kauai County, in 2000, was $20,301, 5.7 percent lower than the average per capita income of the state at $21,525. Similarly, as of 2000 the Median Household Income in Kauai county, at $45,020 was 9.6 percent lower than that of the state at $49,820. Kauai experienced an annual unemployment level of 7.0 percent in 2001, having increased from 6.5 percent in 2000. These rates contrast markedly with that of the state with rates of 4.6 percent in 2001 and 4.6 percent in 2000.

Table 3.4.5-1 shows the number of individuals employed within the main sectors of the economy of Kauai. Retail and service industries dominate the profile, employing more than 60 percent of the workforce at the county level. Tourism, tourism-related services, and government have continued to be the main employment generators since the 1992 hurricane. Currently, the three largest employers on Kauai are the County of Kauai, PMRF, and Wilcox Health Systems.

The visitor industry is of high importance to the economy of Kauai. During 2001, Kauai attracted approximately 1 million visitors. Kauai's share of the Hawaii visitor market was 13.9 percent in 1995 representing a relatively rapid recovery from 1992, when the impact of Hurricane Iniki reduced Kauai's share to 3 percent. Hotel jobs are the heart of the visitor industry. The average monthly employee count for hotel workers numbered 3,693 in 2001 (Hawaii Data Books, 2003a). The local economy also continues to benefit from feature film, television, and commercial production. Since 1992, the film and television industry has contributed an average of $7 million dollars annually to the island's economy. In 2001 the total was $11 million (Hawaii Data Books, 2003b).

Government is the largest single employer on the island, and has remained the least affected by natural disasters or by physical or economic pressures (Hawaii Data Books, 2003a). The number of government employees has grown relatively evenly since 1991. Between 1991 and 2000, the number of federal, state, and local government employees on Kauai grew from 3,450 to 4,100. Of that growth, 77 percent consisted of state employees.

PMRF is the largest federal government employer on Kauai. In September 1997, it employed a total of 870 personnel. Of those, 290 worked directly for PMRF, while the remaining were employed by tenant organizations and subcontractors. The PMRF workforce is composed of 183 DoD civilian personnel, 107 military personnel, 477 contractor personnel, and 103 tenants. The direct economic impact on Hawaii of PMRF, its tenant organizations, contractors and visitors, was $116.6 million in 1996. The PMRF operating budget in 1996 was $109 million, of which $45 million was payroll. PMRF expenditures in 1996 included $8.2 million for construction projects throughout the Hawaiian Islands and $56 million for other purchases. Visitors to PMRF were estimated to have spent $7.5 million in the Kauai economy in 1996.

The major shift in agricultural land use over the last 10 years has been a marked reduction in the cultivation of sugarcane fields across Hawaii, mainly as a result of lowered world prices from foreign sources. On Kauai, the sugarcane downturn resulted in the closure of several significant local operations. In 1994, over 28 percent of Hawaii's sugar cane acreage was located in the five sugar cane plantations of Kauai County. By early 1998, the number of plantations had been reduced to two, and as a result, Kauai has been pursuing a policy of increasing agricultural diversification.
3.5 VANDENBERG AIR FORCE BASE

The existing environment at Vandenberg AFB was described in the Theater Ballistic Missile Targets EA (U.S. Department of the Air Force, 1997b), Booster Verification EA (U.S. Department of the Air Force, 1999), the Evolved Expendable Launch Vehicle Program Supplemental EIS (U.S. Department of the Air Force, 2000), and the Alternate Boost Vehicle Verification Test EA (U.S. Army Space and Missile Defense Command, 2002c). For the most part, those descriptions are still accurate and are not repeated in this document. Rather, for resources that may be affected by ETR activities at Vandenberg AFB, the pertinent resource discussions are summarized and any differences in existing environmental conditions, including new facilities or infrastructure, are noted. The more detailed discussion in the Final EAs and EIS are incorporated by reference and will be made available for review by those who wish more information concerning the existing environment at Vandenberg AFB.

The proposed ETR activities could have an effect on air quality, biological resources, cultural resources, geology and soils, hazardous materials and waste, health and safety, land use, noise, socioeconomics, transportation, and water resources at Vandenberg AFB. These resource areas are summarized below.

Areas that are not expected to be affected sufficiently at Vandenberg AFB to warrant further discussion in this section include airspace, utilities, visual and aesthetic resources, and environmental justice. Airspace impacts would be minimal as described and analyzed in the earlier EAs and EIS cited above. These documents concluded that close coordination with the FAA would result in no adverse effects to airspace from missile flight tests. The use of the required scheduling and coordination process for international airspace and adherence to applicable DoD directives, U.S. Air Force and U.S. Army regulations concerning issuance of NOTAMs, and selection of missile firing areas and trajectories reduces the potential for impacts to airspace. Utility requirements are minimal and would not exceed existing commercial power supplies.

Although the visual resources on Vandenberg AFB may be considered significant by some viewers, much of the area is already developed with the types of structures and activities that are being considered in the Proposed Action. The construction of the IDT along with the supporting infrastructure (fencing, lighting, etc.) would occupy a very small area within the base. In addition, the facilities would be located in areas with a limited number of viewers. The Proposed Action would result in a minor incremental impact to the overall aesthetic value of the potential Proposed Action locations on Vandenberg AFB. Therefore, visual and aesthetic resources will not be analyzed further for Vandenberg AFB. Vandenberg AFB personnel suggested that Environmental Justice could be an issue if the potential exists for disproportionate effects on local Native Americans from the proposed project. However, initial analysis of the Environmental Justice issues, with respect to Chumash Indian uses of cultural areas in the vicinity of the proposed project locations, indicate that there should be no disproportionate impacts. Chumash use of the areas in question should be affected no more than that of other groups who access the base for recreation, fishing, etc. Furthermore, the proposed project requires only infrequent closures of the areas in question. Therefore, Environmental Justice is not an issue warranting in-depth analysis at Vandenberg AFB.
3.5.1 AIR QUALITY—VANDENBERG AIR FORCE BASE

Appendix B includes a definition of air quality and the main regulations and laws that govern it.

3.5.1.1 Region of Influence

For inert pollutants (all pollutants other than ozone and its precursors), the ROI is generally limited to an area extending no more than a few kilometers downwind from the source.

The ROI for ozone may extend much further downwind than the ROI for inert pollutants: however, as the project area has no heavy industry and very few automobiles, tropospheric ozone and its precursors are not of concern. Consequently, for the air quality analysis, the ROI for project operational activities is the Santa Barbara Air Basin, which is part of the South Central Coast Air Basin.

Remote telemetry sites in California would include the use of mobile telemetry support equipment in central California. Activities at these locations would utilize existing paved or graveled areas and be short-term temporary activities. The potential for impacts to air quality is minimal and, therefore, is not discussed further in this document.

3.5.1.2 Affected Environment

Climate

Vandenberg AFB experiences moderate seasonal and daily variation in temperature and humidity due to its coastal location. The temperatures range from 4°C to 24°C (39°F to 75°F) with an annual mean temperature of 14°C (58°F). The rainy season extends from November to April. Average annual precipitation is 33 centimeters (13 inches).

Regional Air Quality

The California Air Resources Board classifies areas of the state in attainment or nonattainment of the California AAQS. In California, air quality is assessed on a county and regional basis. Vandenberg AFB is in Santa Barbara County, which is part of the South Central Coast Air Basin. Santa Barbara County is considered to be in attainment for all AAQS except for state ozone and PM-10 standards. Santa Barbara County has recently met the federal standard for ozone and is in the process of being redesignated by the EPA as being in attainment. Vandenberg AFB has been designated by the EPA to be unclassified for PM-10 but has been designated by California Air Resources Board to be in nonattainment for California AAQS for PM-10. (Santa Barbra County Air Pollution Control District, 2003)

The Santa Barbara County Air Pollution Control District administers regulations for nonvehicular air pollution sources, and is required to monitor air pollution levels to ensure federal and state AAQS are met or develop a plan to meet them (Air Force Center for Environmental Excellence, 1999). The air monitoring station located on Vandenberg AFB is in the south portion of the base.

The ROI for lower-atmosphere air quality resources may extend beyond the project boundaries to include those areas significantly affected by air dispersion and/or commuter traffic. This could include an area as large as the regional air quality basin (South Central Coast Air Basin)
and may affect the maintenance of the NAAQS and the California AAQS for the Vandenberg AFB area.

**Existing Emission Sources**

Prior Vandenberg AFB emission inventory results show that missile launch missions account for less than 1 percent of the total PM-10 and total of carbon monoxide. Since 1991, all new stationary sources of emissions (and modifications) at Vandenberg AFB have applied best available current technology and offset emissions at a 1.2 to 1.0 ratio. Table 3.5.1-1 lists emissions from Vandenberg AFB and Santa Barbara County.

**3.5.2 BIOLOGICAL RESOURCES—VANDENBERG AIR FORCE BASE**

A definition of biological resources and the main regulations and laws that govern their protection are provided in appendix B.

**3.5.2.1 Region of Influence**

The ROI includes areas on Vandenberg AFB and offshore that may be affected by target and interceptor launches from existing and upgraded launch sites, the use of existing sensors, and construction and operation of an IDT site.

Activities at remote telemetry sites in California, such as Pillar Point, would utilize existing paved or graveled areas and be short-term temporary activities. The potential for impacts to biological resources is minimal and therefore will not be discussed further in this document.

**3.5.2.2 Affected Environment**

**Vegetation**

Fourteen major vegetation and habitat types have been described and mapped on Vandenberg AFB. Among these vegetation types, coastal sage scrub and native and non-native grasslands are the major communities found in the proposed project area.
Threatened and Endangered Plant Species

Threatened and endangered plant species with the potential to occur within the ROI are listed in table 3.5.2-1.

CSC California Species of Concern
R Rare
T Threatened

The four known locations of Lompoc yerba santa (*Eriodictyon capitatum*), a federal endangered plant species, occur in western Santa Barbara County. Two of these locations, composed of three groups, are on Vandenberg AFB approximately 12 kilometers (7 miles) south of LF-21 and LF-23. This plant is associated with the central maritime (Burton Mesa) chaparral and bishop pine forest, which are threatened habitat types with limited distribution. (U.S. Environmental Protection Agency, 2001a)

The USFWS has listed the Gaviota tarplant (*Hemizonia increscens ssp. villosa*) as endangered. It occurs within a narrow band of coastal terrace grassland between Gaviota and Santa Barbara (U.S. Environmental Protection Agency, 2001a), southeast of LF-06 (Vandenberg Air Force Base, 2000). It has recently been identified as occurring in two locations on Vandenberg AFB south of and along Point Sal Road (U.S. Department of the Air Force, 1999).

Wildlife

Vandenberg AFB plant communities provide habitat for many resident and migratory animals. The Western fence lizard, garter snake, pocket gopher, California ground squirrel, and deer mouse are typical examples of smaller wildlife species. Also common are brush rabbit, badger, and mule deer. Birds such as ring-billed, Heerman’s, and glaucous-winged gulls, as well as the western wood-pewee, rhinoceros auklet, red-winged blackbird, red-tailed hawk, great horned...
owl, and golden eagle have also been sighted. (U.S. Department of the Air Force, 1997b; Vandenberg Air Force Base, 2000)

Because Vandenberg AFB is near the southern limit of the breeding ranges for many seabird species, a long-term program was begun in 1999 to annually monitor population dynamics and breeding biology of seabirds breeding on Vandenberg AFB. An estimated total of 1,200 seabirds were identified that year. (Point Reyes Bird Observatory, 1999)

The loggerhead shrike (Lanius ludovicianus) and the western burrowing owl (Speotyto cunicularia hypugea) could potentially be present in the project area. Both species are listed as federal and California Species of Concern.

The Pacific harbor seal (Phoca vitulina) is a resident species of Lion’s Head and Point Sal. Counts of harbor seals performed at nine main haul out sites along the coast of Vandenberg AFB average 327 seals. Lion’s Head, the closest site to the proposed project launch sites (figure 3.5.2-1), has been documented as a haul out area and recently as a pupping area for a small number of Pacific harbor seals. The largest number of harbor seals are found at Lion’s Head between September and January. Most harbor seal pupping occurs in March with a 4- to 6-week weaning period. (U.S. Department of the Air Force, 1999)

The California sea lion (Zalophus californianus californianus) does not breed on Vandenberg AFB, but is found along the coastline during the summer (U.S. Department of the Air Force, 1999). Point Sal, which is north of the Base boundary, is the closest area used as a haulout by the California sea lion. Other pinnipeds such as the elephant seal and northern fur seal are observed periodically on the base and can be found in nearby haulout/rookery areas, preferring undisturbed sections of mainland coast and offshore islands or rocks. One such area is just south of Minuteman Beach, which is approximately 3 kilometers (2 miles) from the proposed launch site.

Essential Fish Habitat

Essential Fish Habitat includes those waters and substrate (sediment, hard bottom) necessary to the complete life cycle of fish, from spawning to maturity. The east-west boundary for coastal pelagic species (Pacific sardine and mackerel, northern anchovy, jack mackerel, and squid), groundfish (including species of rockfish, shark, and cod), and highly migratory fish (tunas, marlin, and swordfish) includes all marine and estuary waters from the coast of California to the limits of the Exclusive Economic Zone (the 322-kilometer [200-mile] limit) where the United States has exclusive authority over management of fisheries. Fishing regulations are enforced by Vandenberg AFB security police game wardens.

Threatened and Endangered Wildlife Species

Vandenberg AFB’s diverse habitats support a wide variety of listed species. Those with the potential to occur within the ROI are shown in figure 3.5.2-1 and table 3.5.2-1. A resident population of the federally threatened southern sea otter (Enhydra lutris nereis) has been observed off Purisima Point, typically foraging and rafting in kelp beds; however, semi-migratory individuals may be found all along the coastline. Otters found near the Point Sal area (Friends of the Sea Otter, 2002) are the nearest to the proposed launch site.

**Sensitive Habitat for Listed Wildlife Species on Vandenberg AFB**

Northern Vandenberg Air Force Base, California

**Source:** U.S. Department of the Air Force, 1997b (modified).
The California brown pelican (*Pelecanus occidentalis californicus*), a federal and state endangered subspecies, and the western snowy plover (*Charadrius alexandrinus nivosus*), a federal threatened shorebird, are commonly observed in the Vandenberg AFB area, which provides roosting for the former and nesting and roosting sites for the latter (U.S. Department of the Air Force, 1991). The pelicans roost at Point Sal, northwest of the proposed project launch sites. LF-23 is approximately 1 kilometer (0.6 mile) east of the nearest snowy plover nesting habitat on Minuteman Beach. Other launch sites identified as potential sites for the program are within 1.4 to 5.6 kilometers (0.9 to 3.5 miles) northwest (LF-06), northeast (LF-21), and east (LF-03) of snowy plover nesting habitat. (Wiskowski and Francine, 2002) California brown pelicans and western snowy plovers are also known to use areas near Purisima Point.

Shuman Creek is the main water body closest to the proposed project launch sites. It offers foraging areas for the federally and state endangered California least tern (*Sterna antillarum browni*). The beach at the mouth of Shuman Creek is also occasionally used by the California brown pelican (Vandenberg Air Force Base, 2003). The federally endangered tidewater goby (*Eucyclogobius newberry*) occurs in Shuman Creek. The federally threatened California red-legged frog (*Rana aurora draytoni*) is found in riparian wetland areas in the northwestern Vandenberg AFB portion. It prefers freshwater pools and ponds associated with arroyo willow, cattails, and other thickets of emergent aquatic vegetation. (U.S. Department of the Air Force, 1997b)

San Antonio Creek, located south of Building 1819, is one of the largest streams on base. Several freshwater marshes have been recorded along the San Antonio that, along with the creek itself and the lagoon at its mouth, support both common and rare Vandenberg species (U.S. Department of the Air Force, 1991); the unarmored threespine stickleback (*Gasterosteus aculeatus williamsoni*) and the tidewater goby, federal and state endangered fish, can be found there. This may represent the northern limit for the unarmored threespine stickleback, which uses adjoining feeder streams during the wet season (Pacific Pipeline System, Inc., 1996).

The federally threatened California red-legged frog occurs in the San Antonio Creek and the man-made Mod III Lake located south of Building 1819 on the southern edge of San Antonio Terrace. This lake’s fish, such as gambusia, are all introduced species. The California red-legged frog is found in surrounding riparian areas, as well as in freshwater ponds neighboring the area and Barka Slough. The California red-legged frog is also found in riparian wetland areas in the northwestern Vandenberg AFB portion near Minuteman Beach, and shows a preference for freshwater pools and ponds associated with arroyo willow, cattails, and other thickets of emergent aquatic vegetation. (U.S. Department of the Air Force, 1997b) In March 2001, the USFWS designated 1.6 million hectares (4.1 million acres) in 28 California counties as critical habitat for the threatened California red-legged frog, but excluded Vandenberg AFB since its integrated natural resource management plan provided adequate management for the on-base population (Jumping Frog Research Institute, 2001).

Historical sightings of the recently federally delisted and state endangered American peregrine falcon (*Falco peregrinus*) in the Point Sal area have been reported (U.S. Department of the Air Force, 1999). This raptor has been the subject of an active state reintroduction program since the 1970s (U.S. Department of the Air Force, 1990a).
Environmentally Sensitive Habitat

Dune Systems
The installation envelops one of the major southern California coastal dune systems, with areas still resembling their original condition, and occupies one of the state’s six remaining coastal dune systems. Extensive central foredunes and coastal dune scrub are located on the North Vandenberg coast (U.S. Department of the Air Force, 1991).

Wetlands
Along with a network of swales, several wetlands (including two man-made) occur near Building 1819; the closest is approximately 1.6 kilometers (1 mile) to the northwest. These wetlands, ranging between 0.8 and 2.8 hectares (2 and 7 acres) in size, support such typical species as arroyo willow, wide-leaf cattail, California bulrush, water smartweed, and bog rush.

Critical Habitat
The USFWS recently designated approximately 2,590 hectares (6,401 acres) and 3,929 hectares (9,709 acres) of critical habitat for the Lompoc yerba santa and the Gaviota tarplant, respectively. These endangered plants are only found in coastal areas of Santa Barbara County. Approximately 2,126 hectares (5,253 acres) of critical habitat for these two plants at Vandenberg AFB was excluded. The decision was based on the commitment of Vandenberg AFB to develop and implement protective measures agreed to in its Integrated Natural Resources Management Plan. These measures include establishing Sensitive Resource Protection Areas for the plants in the areas proposed for critical habitat designation and monitoring, survey, enhancement, and restoration activities. (U.S. Fish and Wildlife Service, 2002c)

The USFWS has also designated critical habitat for nesting snowy plovers along the beaches of Vandenberg AFB. Vandenberg AFB is developing a management plan in coordination with USFWS for beach closures during the snowy plover nesting season (1 March through 30 September).

Channel Islands National Marine Sanctuary
In 1980, a 4,294-square kilometer (1,252-square nautical mile) portion of the Santa Barbara Channel was designated as the Channel Islands National Marine Sanctuary. The sanctuary is an area of national significance that encompasses the waters that surround Anacapa, Santa Cruz, Santa Rosa, San Miguel and Santa Barbara Islands and extends from mean high tide to 11 kilometers (6 nautical miles) offshore around each of the five islands. The sanctuary's primary goal is the protection of natural and cultural resources contained within its boundaries. The National Oceanographic and Atmospheric Administration plans to expand the Channel Islands National Marine Sanctuary off the coast of Vandenberg AFB. The study area for this expansion includes an area off the coast of California from south of Point Mugu to north of Point Sal. (National Oceanic and Atmospheric Administration, Channel Islands National Marine Sanctuary, 2002)
3.5.3 CULTURAL RESOURCES—VANDENBERG AIR FORCE BASE

Appendix B includes a definition of cultural resources and the laws and regulations protecting them.

3.5.3.1 Region of Influence

In general, the ROI for cultural resources encompasses areas requiring ground disturbance (e.g., areas of new facility or utility construction) and all buildings or structures requiring modification, renovation, demolition, or abandonment. At Vandenberg AFB this includes the use of existing target launch facilities from existing sites; the use of existing Minuteman launch facilities from existing sites as modified to GBI booster verification test requirements; single and dual launches of GBIs and targets; construction and operation of one IDT; and upgrade of existing facilities, all utilities, and infrastructure to support operations.

Remote telemetry sites in California would include the use of mobile telemetry support equipment in central California. Activities at these locations would utilize existing paved or graveled areas and be short-term temporary activities. The potential for impacts to cultural resources is minimal and, therefore, is not discussed further in this document.

3.5.3.2 Affected Environment

The Integrated Cultural Resources Management Plan (U.S. Air Force, 1997) for Vandenberg AFB is used in part to support the management of the cultural resources found at Vandenberg AFB. This document is used to assist in the preservation of historic buildings, structures, objects, landscapes, and archaeological resources for Vandenberg AFB.

Prehistoric and Historic Archaeological Resources

Numerous archaeological surveys at Vandenberg AFB have identified approximately 2,200 prehistoric and historic cultural sites (Carucci, 2002). Prehistoric sites include dense shell middens, stone tools, village sites, stone quarries, and temporary encampments. Historic artifacts include those typically used in mission establishment, ranching, and military activities. Cultural resource sites located in this area include the site of the former Rancho Guadalupe, which dates from the mission period.

Historic Buildings and Structures

In 1941, the U.S. Army in support of the World War II effort acquired much of the area. Named Camp Cooke, the area served as a training area for armored and infantry units. In 1950 the base was re-activated in support of the Korean War. In 1957, the U.S. Air Force took over the northern 26,305 hectares (65,000 acres) of Camp Cooke and renamed it Cooke AFB. In 1958, the Strategic Air Command took control of the base and renamed it Vandenberg AFB.

Vandenberg AFB has primarily been used to develop several types of intermediate and long-range ballistic missiles and has been largely associated with the launch of military and civilian payloads since the mid-1950s. The 30th Space Wing (30 SW) is currently the host command at Vandenberg AFB and controls the Western Test Range, which conducts military and civilian space and missile launch operations.
Vandenberg AFB currently manages 110 early historic structures and 77 historic Cold War-era facilities. The latter Cold War sites have been determined eligible for listing on the National Register of Historic Places as the result of a recently concluded consultation with the State Historic Preservation Officer. (Carucci, 2002)

**Native Populations/Traditional Resources**

At the time of European contact, the Vandenberg AFB area was occupied by inhabitants who spoke one of the major languages of the Chumashan branch of the Hokan language family. Villages were numerous and typically consisted of domed houses, granaries, ceremonial areas, game fields, and a burial ground. Several villages were located in the area that is now northern Vandenberg AFB.

Even after the first Europeans made contact, the Chumash life and culture continued without the explorers’ influence. It was not until the mid-1700s that the Spanish began to colonize the area and establish missions. In 1901, the Chumash received 30 hectares (75 acres) of reserved land from the U.S. Government, which is presently the only land held by the Chumash people. This reservation is located approximately 32 kilometers (20 miles) east of Vandenberg AFB. The base has maintained a cooperative relationship with the Chumash reservation for several years.

Vandenberg AFB manages approximately 140 Native American traditional cultural properties (Carucci, 2002). Several Chumash-related traditional resources sites have been identified at Vandenberg AFB including villages and campsites, rock art panels, and burial grounds. Among these is Joe’s Pond on the San Antonio Terrace, which is considered to be a traditional resource area by the Santa Ynez Band of Mission Indians (Chumash).

**Paleontological Resources**

The Miocene Monterey Formation and Later Miocene (13 to 25 million years before present) deposits identified at northern Vandenberg AFB have yielded imprints of algae, fish fragments, coprolite, and whalebone. Fossils of both vertebrate and invertebrate animals have been found in the vicinity of Vandenberg AFB (U.S. Army Space and Missile Defense Command, 2002a).

### 3.5.4 GEOLOGY AND SOILS—VANDENBERG AIR FORCE BASE

Appendix B includes a definition of geology and soils and the main regulations and laws that govern them.

#### 3.5.4.1 Region of Influence

The ROI is the footprint of the target and GBI launch pads, and soil areas encompassed by each LHA that might be subject to contamination from launch exhaust emissions and/or potential contamination from unburned fuel in the event of a terminated launch. Construction areas for an IDT and associated trenching for a connecting fiber optic cable are also areas within the ROI.

Remote telemetry sites in California would include Pillar Point. Activities at this location would utilize existing paved or graveled areas and would be a short-term temporary activity. The potential for impacts to geology and soils at this location is expected to be minimal.
3.5.4.2 Affected Environment

Physiography

Vandenberg AFB is located in the Santa Maria Basin, which is bounded on the northeast by the San Rafael Mountains of the Southern Coast Ranges, on the south by the Santa Ynez Mountains of the Western Transverse Ranges, and on the west by the Pacific Ocean. Most proposed system elements are located in the northern portion of Vandenberg. Major physiographic features on the base include, from north to south, the Casmalia and Purisima Hills, San Antonio Terrace, Barka Slough, Lompoc Valley, and Burton Mesa, as well as beaches, rocky headlands, and points. (U.S. Department of the Air Force, 2000)

Geology

Vandenberg AFB is underlain by marine sedimentary rocks of Late Mesozoic age and Cenozoic age. The basal unit underlying the entire area is the Franciscan Assemblage of upper Jurassic age (Dibblee, 1950). The Franciscan Assemblage consists of pervasively sheared marine sedimentary rock and metamorphosed igneous rock with numerous serpentine intrusions (Dibblee, 1988). Extensive folding and faulting throughout the Vandenberg AFB area has created four structural regions; the Santa Ynez Range, the Lompoc lowland, the Los Alamos syncline, and the San Rafael Mountain uplift. (U.S. Department of the Air Force, 1999)

Soils

Surficial deposits at the proposed and alternate facility sites are highly variable and range from weathered bedrock to stream terrace, alluvial fan, and aeolian sheet sands.

Geologic Hazards

Numerous onshore and offshore faults have been mapped within the vicinity of Vandenberg AFB; most are inactive and not capable of surface fault rupture or of generating earthquakes (U.S. Department of the Air Force, 1998a). Four potentially active faults have been mapped on Vandenberg AFB: the Lion’s Head, Hosgri, Santa Ynez River, and Honda (Jennings, 1994) (figure 3.5.4-1). The Lion’s Head fault runs through North Vandenberg AFB, and the Hosgri, Santa Ynez, and Honda faults transect or run adjacent to South Vandenberg AFB. The Lion’s Head, Santa Ynez, and Honda faults show evidence of displacement during the late Quaternary (cut strata of Pleistocene age), and the Hosgri fault has shown evidence of Holocene displacement (less than 10,000 years). (California Department of Conservation, Division of Mines and Geology, 1996)

EXPLANATION

- Base Boundary
- Fault Trace
- U.S. Highway
- Approximate Fault Location
- State Route
- Concealed Fault
- Railroad

The secondary effects of fault rupture are earthquake ground motions, or seismicity. The Western Transverse Ranges, inclusive of the continental borderlands, have historically been in a moderately high seismic region. Within a 32-kilometer (20-mile) radius of the project area, there have been over 90 earthquakes with magnitudes ranging from 3.0 to 7.3 since 1900 (U.S. Department of the Air Force 1998a). Two earthquakes were notable, one in 1812 (M7.1), most likely epicentered in the Santa Barbara Channel, and the other in 1927 (M7.3), offshore near Point Arguello. The 1927 event may have occurred approximately 40 kilometers (24.8 miles) west of Lompoc. (California Department of Conservation, California Geological Survey, 2003) The Hosgri, Lion’s Head, Santa Ynez, and Honda faults are considered by California Geologic Survey to be class B faults, or those lacking paleoseismic data necessary to constrain the recurrence intervals of large events. (California Department of Conservation, Division of Mines and Geology, 1996) Vandenberg AFB is located in a Seismic Zone IV, as defined by the Uniform Building Code (International Conference of Building Officials, 1991), characterized by areas likely to sustain major damage from earthquakes, and corresponds to intensities of VIII or higher on the Modified Mercalli Scale. (U.S. Department of the Air Force, 1998a)

3.5.5 HAZARDOUS MATERIALS AND HAZARDOUS WASTE—VANDENBERG AIR FORCE BASE

The relevant aspects of hazardous materials/waste management include the applicable regulations and procedures for hazardous materials usage and hazardous waste generation, and management programs for existing hazardous waste-contaminated sites within the ROIs.

Appendix B includes a general description of hazardous materials and waste.

3.5.5.1 Region of Influence

The ROI for potential impacts related to hazardous materials/wastes includes areas of north Vandenberg AFB to be used for launch activities, pre-launch site preparation, and in areas where liquid propellant would be stored and handled.

3.5.5.2 Affected Environment

Hazardous Materials and Hazardous Waste

In 1991, the State of California developed a state EPA called Cal/EPA. This agency regulates air, water, pesticides, integrated wastes, toxic substances and environmental health hazard assessments. Although the federal regulations still are enforced, California has developed far more stringent environmental regulations than has been promulgated federally.

Hazardous Materials Management

Hazardous materials use at Vandenberg AFB must conform to applicable federal, state and local laws and regulations. Hazardous materials obtained from off base suppliers are coordinated through Vandenberg AFB’s Hazmart Pharmacy. A base supply contractor runs the Hazmart Pharmacy and (in accordance with U.S. Air Force Instructions) inventories all hazardous materials, whether purchased by the U.S. Air Force or its contractors. Hazardous materials are tracked using Environmental Management System software. These procedures are in accordance with the 30 SW Hazardous Materials Management Plan.
Most hazardous materials fall into two use categories: materials used in base maintenance activities and those used in various launch operations. Numerous types of hazardous materials are used to support the various missions and general maintenance operations at Vandenberg AFB. Categories of hazardous materials used during current launch activities include POL, volatile organic compounds, corrosives, refrigerants, adhesives, sealants, epoxies, and propellants.

Spills of hazardous materials are covered under the Hazardous Materials Emergency Response Plan. This plan ensures that adequate and appropriate guidance, policies, and protocols regarding hazardous material incidents and associated emergency response are available to all installation personnel.

**Hazardous Waste Management**

Hazardous wastes at Vandenberg AFB are regulated by the Resource Conservation and Recovery Act (RCRA) (Title 40 CFR 260-280) and the California EPA Department of Toxic Substances Control, under the California Health and Safety Code, Title 22, Division 20, Chapter 6.5, Sections 25100 through 25159, and the California Administrative Code, Sections 25100 through 67188. These regulations require that hazardous wastes be handled, stored, transported, disposed of, or recycled.

The Vandenberg AFB Hazardous Waste Management Plan (dated 15 November 2000), describes procedures for packaging, handling, transporting, and disposing of hazardous waste. Hazardous wastes generated during Vandenberg AFB activities are initially collected at the point of generation and, if not reused or recycled, transported to the collection-accumulation point managed by the base Environmental Flight. Here it is containerized and segregated by type. Following initial containerization, waste may remain at the collection-accumulation point for up to 90 days, at which point all hazardous waste must be transported to the off-site Treatment, Storage, and Disposal Facility (Vandenberg Air Force Base, 2001).

**Pollution Prevention/Recycling/Waste Minimization**

**Installation Restoration Program**

Vandenberg AFB is not listed on the National Priorities List. IRP sites at Vandenberg AFB are being addressed in a manner generally consistent with the Comprehensive Environmental Response, Compensation, and Liability Act process. As of the end of 1996, 36 IRP sites were in the remedial investigation/feasibility study stage including those undergoing Interim Remedial Actions. In addition, 40 sites are in the Remedial Action phase. Sixty sites have been recommended for No Further Remedial Action Planned, with state concurrence.
Underground and Aboveground Storage Tanks

USTs and ASTs at Vandenberg AFB are installed and maintained in compliance with appropriate local, state, and federal standards and regulatory requirements.

Any installation, modification or removal of USTs or ASTs must be approved by the base Storage Tank Manager in the Environmental Flight.

Asbestos, Lead-Based Paint, and Polychlorinated Biphenyls

Disposal of friable asbestos is not permitted on Vandenberg AFB. Asbestos management and abatement at Vandenberg AFB is in compliance with appropriate local, state, and federal standards and regulatory requirements.

The Vandenberg AFB Hazardous Waste Management Plan (dated 15 November 2000), specify all procedures for sampling, handling and disposing of lead-based paint and PCBs.

Liquid Propellants and Other Toxic Fuels

Existing procedures assure safe handling of liquid propellants and other toxic materials. Current operations include storage and handling of GBI and EKV propellants.

3.5.6 HEALTH AND SAFETY—VANDENBERG AIR FORCE BASE

Appendix B includes a general description of health and safety.

3.5.6.1 Region of Influence

The ROI for potential impact related to the health and safety of workers includes the work areas associated with transportation of missile components, pre-launch storage and handling, missile launch, and post-launch activities. The population of concern would predominantly consist of the contractor, military, and government civilian personnel directly involved with GMD ETR program operations.

The ROI for potential impact related to public health and safety includes any areas affected by transport of missile components and immediately bordering Vandenberg AFB that may be affected by launch hazard areas.

Remote telemetry sites in California would include Pillar Point. Activities at this location would utilize existing paved or graveled areas and be short-term temporary activities. Because of the type of emissions and the limited power output, the potential for impacts to health and safety is expected to be minimal and, therefore, is not discussed further in this document.

3.5.6.2 Affected Environment

Range Safety

Vandenberg AFB is involved in the ongoing test and evaluation of various missiles and space launch vehicles, with safe procedural practices as a primary objective. To accomplish this, an
aggressive safety evaluation and control system has been implemented, based on more than 40 years experience in test and evaluation.

Proposed on-base program operations must receive prior approval, accomplished by the user through presentation of the program to Space Wing/Safety Office (30 SW/SE). All safety analyses, SOPs, and other safety documentation applicable to those operations affecting Vandenberg AFB, or the Western Range Area and its controlled range space, must be provided, along with an overview of mission objectives, support requirements, and schedule. The 30 SW/SE evaluates this information, ensuring that all Western Range Area safety requirements are met.

Vandenberg AFB possesses significant emergency response capabilities that include its own Fire Department, Disaster Control Group, and Security Police Force, in addition to contracted support for handling accidental releases of regulated, hypergolic propellants and other hazardous substances. The Readiness Flight (30 CES/CEX) manages the overall base emergency response program and is responsible for developing and updating the Vandenberg AFB Hazardous Material Emergency Response Plan. Additionally, the 30 CES/CEX chairs the Hazardous Materials Planning Team, ensures that follow-on elements of the Disaster Control Group are assembled as required by the On-Scene Commander in the event of a release response, and maintains training certificates for spill response team members. (U.S. Department of the Air Force, 1999)

According to the Santa Barbara County Integrated Hazardous Materials Management System Operation Agreement, the base Fire Department approves and maintains the business plans and hazardous material inventories prescribed by the California Health and Safety Code, which are developed by organizations assigned to or doing business on the base. This information can be retrieved electronically in the event of an emergency. Additionally, the base Fire Department conducts onsite facility inspections, as required, to identify potentially hazardous conditions that could lead to an accidental release. It should be noted that the Vandenberg AFB Fire Department is advised of all operations involving the transfer of hypergolic propellants on the base. During launch operations, Fire Department response elements are pre-positioned to expedite response in the event of an anomaly. (U.S. Department of the Air Force, 1999)

Preceding operations that may involve ground impact of objects within the range, an evaluation is made to ensure that populated areas, critical range assets, and civilian property susceptible to damage are outside potential impacts limits. A NOTMAR and a NOTAM are published and circulated in accordance with established procedures to provide warning to mariners and pilots (including recreational users of the range space and controlled sea areas) concerning any potential impact areas that should be avoided. Radar and visual sweeps of hazard areas are accomplished immediately before operations to ensure evacuation of non-critical personnel. Before missile flight operations, the performance of all target missiles will be evaluated by 30 SW/SE to determine whether or not a Flight Termination System is warranted; if so, its use must be in accordance with Eastern and Western Range (EWR) 127-1, Range Safety Requirements. In addition, proposed trajectories are analyzed and a permissible flight corridor is established. A missile that strays outside its corridor is considered to be malfunctioning and to constitute an imminent safety hazard.
As stated earlier, test mishaps for target missiles are defined in terms of three scenarios: missile failure on the launch pad, termination of a flight shortly after liftoff, and termination of a flight after the missile has exited the vicinity of the launch site.

Termination of a flight on the launch pad is characterized by either detonation of the booster or a conflagration in which the propellant burns but does not explode. An ESQD surrounding the launch pad would be calculated based on the equivalent explosive force of all propellant and pyrotechnic materials contained in the flight vehicle. For the current target systems, the ESQD is 381 meters (1,250 feet). During all launch activities, provisions will be made in accordance with EWR 127-1 to maintain a stand-by emergency response team near the launch site to ensure immediate response and rapid control in the event of an accident.

Termination of a flight on the launch pad or shortly after liftoff would result in all hazardous debris being contained within the Flight Hazard Area (FHA). Non-essential mission personnel are excluded from this area during launch operations; personnel required to work within FHA boundaries will be protected in hardened shelters, such as bunkers or blockhouses. The FHA is based on a risk of $1 \times 10^{-5}$ to a single individual on the FHA boundary during a launch. The Flight Caution Area (FCA) is the area outside the FHA where personal injury could occur because of early flight failure or termination. The FCA is based on a risk of $1 \times 10^{-6}$ to single person on the FCA boundary during a launch. Access to the FCA is also limited to mission-essential personnel.

In accordance with existing Vandenberg SOPs, 30 SW/SE will ensure that the debris from the termination of a flight will fall into areas verified clear before the launch (U.S. Army Space and Strategic Defense Command, 1994).

The launch scenario will be planned to ensure debris will not fall within a 4.8-kilometer (3-mile) distance of the California coast (U.S. Department of the Air Force, 1997b). Any debris falling on Vandenberg AFB land will be handled in accordance with Vandenberg emergency response plans, based upon the 1996 *North American Emergency Response Guidebook* (U.S. Department of the Air Force, 1997b).

Launch vehicle mishaps (i.e., accidents involving any launch vehicle operation) are handled by various emergency support teams on base. Some of these procedures include authorization to enter an accident area, control procedures for monitoring trains, and salvage procedures. Several distinct teams of qualified individuals are available to respond to emergencies that might occur during a launch. These teams include the Specialized Operation Support Team, the On-Scene Disaster Group, the Missile Potential Hazard Team, and the Launch Support Team. The Southern Pacific Transportation Company railroad crosses Vandenberg AFB and owns the railroad property. Most launches fly over the railroad. The 30 SW has procedures for train protection and subsequent "hold" or "proceed" decisions during launch operations.

**Management of Risks due to Rocket Propellant and Motor Exhaust Constituents Exposures**

The exposure criteria used in EWR Safety Programs are used to fulfill toxic hazard and risk management requirements and policies. The objective of these programs is to maximize range operability without compromising public and worker safety. The Headquarters Air Force Space Command Surgeon General (HQ AFSPC/SG) has recommended exposure criteria for some of
the current solid- and liquid-rocket propellants and their combustion by-products. HQ AFSPC/SG has also recommended that the EWRs use a risk-management based approach for developing toxic launch commit criteria consistent with current human toxic exposure criteria and coordinated with Local Emergency Planning Committees and local agencies, as needed. In an effort to comply with this recommendation, the EWR Safety offices developed a toxic risk-management based approach designed to maintain an exposure criteria less than or equal to $30 \times 10^{-6}$ with an individual risk of $1 \times 10^{-6}$ over the varying population densities. This approach takes into account probability of catastrophic failure, concentration, direction, dwell time, and emergency preparedness procedures. This risk level presents no greater risk to the general public for launch and flight of launch vehicles and payloads than that imposed by overflight of conventional aircraft.

Vandenberg AFB has safety procedures in place, which are described below, to protect the public and sensitive receptors from potential toxic emissions.

The Western Range has a three-tiered, three-zone deterministic approach plus a probabilistic approach to protecting against harmful toxic exposures of hydrogen chloride. The Western Range implements safety measures that are designed to protect mission essential and non-mission essential persons. Before launch, the Rocket Exhaust Effluent Diffusion Model is used to locate toxic zones.

There are three zones for assessing an individual’s proximity to toxic combustion products, including those that could result from a launch failure. Zone 1 is an area where airborne concentrations of any toxic product are equal to or exceed Tier 1 levels but are less than Tier 2 levels. Zone 2 is an area where airborne concentrations of any toxic product are equal to or exceed Tier 2 levels but are less than Tier 3 levels. Zone 3 is an area where airborne concentrations of any toxic product range from a low defined by Tier 3 to an unknown high. Table 3.5.6-1 describes the Tier levels.

Before launch, the Rocket Exhaust Effluent Diffusion Model is run to ensure that any mission essential persons within a Zone 2 (having predicted hydrogen chloride concentrations exceeding the Tier 2 level [see 30 SWI 91-106, 1998]) are aware of being in a Zone 2, have personnel protection equipment, and have a pre-determined route of departure. If mission essential personnel do not meet these requirements, then they are relocated out of the zone. Any non-mission essential people on-base are also moved, if feasible. If they cannot be moved, or if they are off-base and not subject to being moved, then their locations and exposure are taken into account in the risk assessment procedure.

NOTES:

1 Tier 1 – This exposure level and above is defined as the discomfort or mild-effect level. There is little risk to the average person. This exposure poses no hazard to normal and healthy individuals. Sensitive individuals (i.e., asthmatics and bronchitics) may experience some adverse effects, which are reversible. Tier 1 represents exposure guidelines for sensitive members of the general public (off-base) who may involuntarily and unknowingly be exposed. Recommended action, if this tier is exceeded, is similar to a Stage 3 air pollution alert: Notify the public of the release through an advertised announcement particular to an event or a published annual notice that sensitive populations should be advised that there is a possibility of exposure to the effluent and advise of mitigating precautions.

2 Tier 2 – This exposure level and above is defined as the disability or serious-effect level. All effects are reversible. There are no serious impacts on personnel’s ability to complete the mission identified. There is some risk to an average individual. Military and employees voluntarily accept exposure up to Tier 2 concentrations. The consent implies knowledge of the exposure concentrations and the consequences of possible exposure. Tier 2 represents personnel who have knowledge of the event and understand the possibility and consequences of possible exposure (on-base personnel). Personnel are advised to seek immediate protection (shelter in place) or evacuate for concentrations exceeding the Tier 2 limit.

3 Tier 3 – This exposure level and above is defined as a life-threatening-effect level. Irreversible harm may occur with possible impact on a person’s ability to complete the mission. Personnel in an area (event personnel) where Tier 3 exposure may occur have given informed consent and are trained regarding the possible life-threatening situations. Exposures up to Tier 3 concentrations permit an individual to seek shelter or don respiratory protection. Concentrations predicted in excess of Tier 3 concentrations require immediate evacuation to prevent exposure.

4 Time-weighted average exposure concentration. The time period indicated in parentheses is the time over which the concentration measurements will be measured and averaged.

5 Ceiling limit. A peak concentration that must not be exceeded during the exposure period.

6 Exposure criteria recommended by HQ AFSPC/SG.

7 Exposure criteria recommended by AL/OE and endorsed by HQ AFSPC/SG.

A-50 = Aerozine-50 (50 percent by weight unsymmetrical dimethylhydrazine and anhydrous hydrazine)

HCl = hydrochloric acid

HNO\(_3\) = nitric acid

HQ AFSPC/SG = Headquarters Air Force Space Command/Surgeon General

min = minutes

MMH = monomethyl hydrazine

NR = no recommendation

N\(_2\)H\(_4\) = anhydrous hydrazine

NO\(_2\) = nitrogen dioxide

ppm = parts per million

UDMH = unsymmetrical dimethylhydrazine

The Western Range toxic risk-assessment-based recommendation to launch or not to launch is based on the results of the Launch Area Toxic Risk Analysis (LATRA) program (i.e., risk assessment program) that evaluates the risk to people, regardless of whether they are mission essential or non-mission essential. Among other criteria in determining whether to launch, the
LATRA accounts for (1) whether people are sheltered or unsheltered; (2) whether they are healthy or sensitive individuals; and (3) the probability of a catastrophic launch failure.

Regional Safety

Regionally, Santa Barbara County prepared a Hazardous Material Response Plan that is used for countywide disaster response. Cities and communities in the county are required to have their own emergency response plans that were incorporated by the county into a comprehensive Multihazard Functional Plan, which specifies actions to be taken in case of a local disaster. The city of Lompoc adopted its Multihazard Functional Plan in 1989 and amended it in 1994. Because of the potential for Vandenberg AFB operations to affect off-base areas, Vandenberg AFB plays a prime role in regional emergency planning (U.S. Department of the Air Force, 1997b).

The city of Lompoc and Vandenberg AFB have entered into a mutual aid agreement, which allows emergency units from either Lompoc or Vandenberg AFB to provide each other with assistance in the event of an emergency. A "hotline" exists between the city of Lompoc and Vandenberg AFB in order to immediately notify the city in case of a major accident on the base. In the event of an emergency involving a launch mishap in Lompoc, Vandenberg AFB would assume control and could set up a national defense area if protected material were involved in the accident.

In the event of a launch vehicle impacting other areas outside Vandenberg AFB, the On-Scene Disaster Control Group from Vandenberg AFB would respond to the accident upon request of the county. County agencies would be used to help in the evacuation and possible fire control for such an incident. Military personnel would assume responsibility for disaster control in the immediate impact area.

Impact debris corridors have been established off the Santa Barbara County coast between Point Sal and Point Conception. These corridors were established to meet security requirements and reduce the hazard to persons and property during a launch-related activity. Impact debris corridors are established through the designation of debris impact areas for each specific launch as discussed in range safety procedures. These corridors are plotted for all launches. Figure 3.5.6-1 presents example impact debris corridors for a typical launch from LF-06 and LF-21.

Zone closures are announced daily over various radio frequencies and posted in harbors along the coast. The 30 SW Flight Analysis notifies the 30 Range Squadron of areas that are hazardous to aircraft (i.e., impact debris corridors) for all normally jettisoned and impacting stages by 30 working days before launch. The 30 Range Squadron notifies the FAA, Los Angeles Center or Oakland Center, so that the information can be disseminated through a NOTAM. Restricted airspace areas are active and controlled according to EWR 127-1 Range Safety Requirements, Safety Operating Instructions, 30 SW regulations, and FAA directives and regulations. Control of air traffic in FAA-designated areas around the launch head are maintained and coordinated between the Aeronautical Control Officer and FAA to ensure that aircraft shall not be endangered by launches. The Air Route Surveillance Radar surveys the restricted airspace beginning 15 minutes before the scheduled launch time and until the launch is complete.
Figure 3.5.6-1

Impact Debris Corridors for a Typical Launch from LF-06 and LF-21

Vandenberg Air Force Base, California

Source: Vandenberg Air Force Base, 2002b (modified).

EXPLANATION
- Vandenberg Air Force Base
- Water
- Santa Barbara County
- Santa Barbara County Urban Areas
- LF-6 Debris Corridor
- LF-21 Debris Corridor

Scale
- 0 3 6 kilometers
- 0 1.85 3.7 miles

GMD ETR Final EIS
The 30 SW also ensures that a NOTMAR within the impact debris corridor is disseminated beginning 30 working days before launch. Information regarding impact debris corridors is distributed to surface vessels when the 30 SW sends written notification of impact debris corridors to be published weekly in the U.S. Coast Guard Long Beach Broadcast to Mariners. Broadcasts by U.S. Coast Guard Long Beach provide the latest available hazard information to offshore surface vessels. 30 SW has developed procedures related to evacuating or sheltering personnel on offshore oil rigs during launch operations. These procedures pertain to offshore platforms located west of 120 degrees 15 minutes longitude. The 30 SW Chief of Safety notifies 30 Range Squadron of future launches, and 30 Range Squadron notifies the Minerals Management Service, Department of the Interior, to notify oil rig personnel of a future launch. The Minerals Management Service will first notify the oil rig operator 10 to 15 days before a launch to prepare for possible sheltering or evacuation. The second notice is given 24 to 36 hours before the launch confirming the requirement to shelter or evacuate. The third notice is given by Frontier Control to provide final notice before, during, and after securing the operation. Additional notices are sent as required. Oil rig operators are notified to shelter or evacuate personnel according to the Rocket Exhaust Effluent Diffusion Model of toxic vapor plumes and potential impact of launch debris.

There are two public beaches in the ROI: Point Sal Beach State Park to the north and Ocean Beach County Park at the terminus of SR 246 near the division between North and South Vandenberg AFB.

Point Sal Beach State Park and Ocean Beach County Park are within the ROI for Minuteman and Delta missile launches from North Vandenberg. Ocean Beach County Park is also closed for Atlas and Titan launches. Access roads to both parks can be closed and visitors can be evacuated under an agreement between Vandenberg AFB and Santa Barbara County. Currently closure procedures occur an average of 9 to 10 times per year. All closure and evacuation agreements have been consolidated under an Evacuation Agreement, giving Vandenberg AFB the right to evacuate and close the beaches up to 48 hours before a launch. (U.S. Department of Air Force, 1997b)

Base flight safety requires that there be no overflight of civilian property on the coastline, and that there be no overflight of any of the Channel Islands, except San Miguel Island. Although direct overflight of the beaches does not occur, there is the possibility of debris from a launch anomaly impacting the beaches. In order to protect park visitors, Vandenberg AFB, the County Parks Department, the County Sheriff, and the California Highway Patrol have agreed to close the parks upon request during launches affecting the beaches.

3.5.7 LAND USE—VANDENBERG AIR FORCE BASE

Appendix B includes a definition of land use and the main federal land management responsibilities that govern its protection.

3.5.7.1 Region of Influence

The ROI for the land use generally includes Northern Santa Barbara County region within and adjacent to the boundaries of Vandenberg AFB that are potentially affected by the launch of target and GBI missiles and the construction, modification, and operation of support facilities associated with the Proposed Action.
Remote telemetry sites in California would include Pillar Point. Activities at this location would utilize existing paved or graveled areas and would be a short-term temporary activity. The potential for impacts to land use at Pillar Point is expected to be minimal and, therefore, is not discussed further in this document.

3.5.7.2 Affected Environment

Vandenberg AFB, located in western Santa Barbara County in south central California, is approximately 88 kilometers (55 miles) northwest of Santa Barbara, and 225 kilometers (140 miles) northwest of Los Angeles. The base’s 39,821 hectares (98,400 acres) are approximately 6 percent of the total land area of Santa Barbara County. Numerous communities are located within 16 kilometers (10 miles) of the base but are separated by wide buffers of agricultural areas. These buffer lands are the result of efforts between the nearby cities of Lompoc and Santa Maria and the Santa Barbara County functioning as local planning authorities for lands adjoining the base. (U.S. Department of the Air Force, 1997b) Their general plans include the designation of compatible land uses between adjacent lands and Vandenberg AFB. Neither the county nor neighboring cities have any land use authority over Vandenberg AFB land because of its federal land status. Furthermore, Vandenberg AFB determines its own land use and zoning regulations. (U.S. Department of the Air Force, 1998a)

Approximately 5 percent of the base has been disturbed, leaving the remainder in its natural state (U.S. Department of the Air Force, 1997b). According to Vandenberg AFB’s Comprehensive Plan, the base has allocated the following land use areas: airfield operations and maintenance/space and missile launch, industrial, outdoor recreation, open space, airfield, and cantonment. The cantonment area includes residential, administrative, industrial, recreational, open space, airfield, and community land uses. Approximately 90 percent of the land use on Vandenberg AFB is open space, followed by industrial (approximately 6 percent) and airfield operations and maintenance/space and missile launch (approximately 2 percent). (U.S. Department of the Air Force, 1998a)

Vandenberg AFB is divided into northern and southern regions by the Santa Ynez River and West Ocean Avenue. Development has occurred primarily on the northern region of the base whereas the southern portions remain primarily undeveloped. (U.S. Department of the Air Force, 1998a) The primary ROI for the proposed activities is North Vandenberg AFB.

Vandenberg AFB’s 56 kilometers (35 miles) of undeveloped coastline exist as a fraction the 840 mile long California Coastal National Monument composed of small, federally owned islands, rocks, and exposed reefs. Currently the Bureau of Land Management has begun the process to prepare a Resource Management Plan for the California Coastal National Monument (U.S. Environmental Protection Agency, 2002).

As of November of 1999 Congress directed the National Park Service to conduct a resource feasibility study to determine whether the Gaviota Coast or any portion of it is eligible and/or suitable to be managed as an entity of the National Park System (National Park Service, 2002). The Gaviota Coast is composed of 80,937 hectares (200,000 acres) from Coal Oil Point on the University of California Santa Barbara campus in Isla Vista to Point Sal at the northern boundary of Vandenberg AFB. The Park Service study focuses on private lands, four state parks, parts of Los Padres National Forest, and all of Vandenberg AFB. (U.S. Air Force Headquarters, 2002)
The feasibility study, its release for public review and recommendation to the U.S. Congress are expected in early 2003 (National Park Service, 2002).

Limited public access to North Vandenberg AFB’s shoreline provides various opportunities for recreational activities in the vicinity. Two public access parks that exist on or immediately adjacent to the base include Point Sal Beach State Park, which borders the northern most boundaries, and Ocean Beach County Park located approximately midway along the coast edge of Vandenberg AFB. Both provide opportunities for picnicking, surf fishing, and general beach activities (U.S. Department of the Air Force, 1998a).

All public access closures and evacuation agreements allow the base the right to evacuate and close the beaches days before launch (U.S. Department of the Air Force, 1997b). Most park closures only occur for 3 to 4 hours. However, unstable weather conditions, or any mechanical problems, resulting in an abort launch or launch rescheduling may prolong a closure (U.S. Department of the Air Force, 1998a).

Coastal Zone Management

A federal activity in or affecting a coastal zone requires preparation of a Coastal Zone Consistency Determination by the proponent in coordination with the Vandenberg AFB Environmental Division. The area along the western coast of Vandenberg AFB is within the North Coast Planning Area. The base’s coastal zone extends inland from about 1.2 kilometers (0.75 mile) at the northern boundary to 7.2 kilometers (4.5 miles) at the southern end. The widest portion of the coastal zone occurs at San Antonio Creek and south of Cañada Honda Creek to the southern boundary. (U.S. Department of the Air Force, 1998)

3.5.8 NOISE—VANDENBERG AIR FORCE BASE

Appendix B includes a definition of noise and the main regulations and laws that govern it.

3.5.8.1 Region of Influence

The area immediately surrounding Vandenberg AFB is mainly undeveloped and rural, with some unincorporated residential areas within the Lompoc and Santa Maria valleys. The two urban areas in the region are the cities of Lompoc and Santa Maria, which support a few localized industrial areas. Sound levels measured for most of the region are normally low, with higher levels appearing in industrial areas and along transportation corridors. The minimum ROI for noise analysis is the area within the maximum sound level (Lmax) = 85 dB contours generated by program activities.

Remote telemetry sites in California would include Pillar Point. Activities at this location would be short-term temporary activities that include the operation of generators as primary or backup power. Although specific locations have not been identified, the noise from the generators would dissipate to minimal levels. The potential for noise impacts is expected to be minimal and, therefore, is not discussed further in this document.
3.5.8.2 Affected Environment

The immediate area surrounding Vandenberg AFB is largely composed of undeveloped and rural land, with some unincorporated residential areas in the Lompoc and Santa Maria valleys and Northern Santa Barbara County. The cities of Lompoc and Santa Maria, which make up the two urban areas in the region, support a small number of localized industrial areas. Sound levels measured for the area are typically low, except for higher levels in the industrial areas and along transportation corridors. The rural areas of the Lompoc and Santa Maria valleys typically have a low over all noise levels, 40 to 45 dBA. Infrequent aircraft flyovers and missile launches from Vandenberg AFB increase noise levels for a short period of time (U.S. Army Space and Missile Defense Command, 2002a).

Noise at Vandenberg AFB is typically produced by automobile and truck traffic, aircraft landings and takeoffs, and space vehicle launches. Railroad traffic is also a significant source of noise. Existing noise levels on Vandenberg AFB are typically low; the higher levels occur near industrial facilities and transportation routes. Vandenberg AFB follows state regulations concerning noise, and maintains a Community Noise Equivalent Level (CNEL) equivalent to 65 dBA for off-base areas (U.S. Army Space and Missile Defense Command, 2002a).

Missile launches from Vandenberg AFB produce less frequent but more intense sources of noise in the region. Current launches include Minuteman missiles and Delta II rockets launched from the North Base and Titan and Atlas missiles from the South Base. Typical noise levels for familiar sources and Vandenberg AFB launch vehicles, such as the Minuteman, are summarized in table 3.5.8-1 and discussed below (U.S. Army Space and Missile Defense Command, 2002a).

</tbody>
</table>

Source: U.S. Army Space and Missile Defense Command, 2002a

Noise levels in Lompoc and Santa Maria from Minutemen missile launches would be expected to be a maximum of 49 dBA and 74 dBA, respectively. Noise from a Titan IV launched from Space Launch Complex (SLC)-4 in August 1993 was measured at six locations. The Titan IV is the largest launch vehicle in the U.S. military inventory and has the greatest potential for noise impacts. Measurement sites were located downrange at nominal distances from the launch pad. Data were tape recorded at all sites and processed into appropriate sound levels. Direct sound level meter measurements were made as shown in table 3.5.8-2. Of interest is the measurement at the 13,146-meter (43,129-foot) site in the city of Lompoc: A-weighted sound pressure level was 88.0 dB, A-weighted sound exposure level was 93.7 dB, and output sound pressure level was 112.8 dB. Because launches from all of these facilities would occur
intermittently, the resulting noise would not cause an increase in the average (equivalent sound level $L_{eq}$, day-night average sound level $L_{dn}$, or CNEL) noise levels in nearby areas. The cumulative quantities $L_{dn}$ and CNEL are based on sounds that occur on a regular basis, at least every day, and usually many times per day. Missile launches are relatively infrequent, at rates well below those needed for $L_{dn}$ or CNEL to be meaningful (U.S. Department of the Air Force, 1998a).

3.5.9 SOCIOECONOMICS—VANDENBERG AIR FORCE BASE

Appendix B includes a general definition of socioeconomics.

3.5.9.1 Region of Influence

The ROI for socioeconomics is defined as the communities and areas surrounding Vandenberg AFB. Primary areas of analysis will concern the larger, more populous communities, including the cities of Lompoc and Santa Maria, as well as wider Santa Barbara County.

3.5.9.2 Affected Environment

Vandenberg AFB is in the western part of unincorporated Santa Barbara County, California. The Santa Ynez River and State Route (SR)-246 divide the base into North and South Vandenberg AFB. North Vandenberg AFB generally includes the developed portions of the base, whereas South Vandenberg AFB includes primarily open space. The city of Lompoc lies to the east, the city of Santa Maria to the northeast, and the city of Guadalupe to the north. Two unincorporated communities, Vandenberg Village and Mission Hills, are north of the city of Lompoc. Also, Vandenberg AFB is considered a Census Designated Place and data regarding Vandenberg AFB via the 2000 census has been examined.

Population and Housing

The total population of Santa Barbara County increased from 369,608 persons in 1990 to 399,347 persons as of 2000 (8.04 percent) (U.S. Census Bureau, 2003b). The city of Santa Barbara, with a population of 92,325 people as of 2000, was the largest city in the county and contained 23.1 percent of the county population. Of the communities adjacent to Vandenberg
AFB, the city of Santa Maria, with 77,423 persons is the most populous, followed by the city of Lompoc with 41,103 people. (County of Santa Barbara, 2003) Casmalia is a much smaller community with less than 200 people as of 2000. Vandenberg AFB itself showed a larger population than the unincorporated communities immediately adjacent to the base (County of Santa Barbara, 2003).

As of 2000, there were an estimated 142,901 housing units within Santa Barbara County (U.S. Census Bureau, 2003b) of which 37,076 housing units were located within the City of Santa Barbara and 22,847 and 13,621 units were located in Santa Maria and Lompoc respectively (County of Santa Barbara, Department of Planning and Development, 2003). As of 2000, 1,992 units were located within Vandenberg AFB and 2,366 and 1,072 units were located in the communities of Vandenberg Village and Mission Hills respectively.

In addition, the Bureau of the Census reported that vacancy rates of rental housing within Santa Barbara County and city averaged 2.8 percent and 2.3 percent respectively during 2000 (U.S. Census Bureau, 2003b). These were marginally lower than the average vacancy rates of 4.0 percent and 3.1 percent for the cities of Lompoc and Santa Maria respectively. While Vandenberg Village showed a 3.6 percent vacancy rate, vacancy rates within Vandenberg AFB and Mission Hills, at 2.2 percent, and 2.1 percent respectively, more closely resembled the county average levels.

Income and Employment

The U.S. Bureau of the Census reported that the per capita income in Santa Barbara County, as of 2000, was $23,059, only slightly higher (1.5 percent) than the average per capita income of the state at $22,711 (U.S. Census Bureau, 2003c). Conversely, as of 2000 the median household income in Santa Barbara County, at $46,677 was only slightly lower (1.6 percent) than that of the state, at $47,443 (U.S. Census Bureau, 2003c). Table 3.5.9-1 shows the number of individuals employed within the main sectors of the economy of Santa Barbara County. Retail and service industries dominate the profile, employing approximately 60 percent of the workforce within the county.

Santa Barbara County’s economic growth has been driven by the expansion of local telecommunications, computer and software, medical devices, and electronics firms (Cumulus Media, Inc., 1999). Major employers include the University of California, Vandenberg AFB, Lockheed Martin, Vons/Williams Brothers Stores, and Raytheon Systems (Cumulus Media, Inc., 1999). The University of California, Santa Barbara has an enrollment of 19,000 students and is the area’s largest employer with 8,660 employees. The University of California, Santa Barbara has an annual budget of $400 million, with $240 million being spent locally. In addition, the student population adds over $131 million annually to the local economy. Vandenberg AFB employs over 1,500 civilian workers and has a military population of 3,600. (Cumulus Media, Inc., 1999)

### 3.5.10 TRANSPORTATION—VANDENBERG AIR FORCE BASE

Appendix B includes a general description of transportation.

#### 3.5.10.1 Region of Influence

The ROI for the resources addressed in this EIS is the ground, ocean, and aviation transport systems within or immediately adjacent to Vandenberg AFB and the flight test corridor that has been established.

#### 3.5.10.2 Affected Environment

**Aviation Transportation**

There are four airports within the surrounding area of Vandenberg AFB. These include Santa Barbara Municipal, Santa Ynez, Lompoc, and Santa Maria Public airports. Vandenberg AFB also maintains its own runway, which is capable of handling large aircraft (U.S. Army Space and Missile Defense Command, 2002a).

**Ground Transportation**

*Regional*

Vandenberg AFB is accessible by U.S. 101, which connects the base with San Francisco to the north and Santa Barbara to the south. SR-1, SR-135, and SR-246 provide access to the base from U.S. 101. (U.S. Department of the Air Force, 1998a)
Local
The majority of the workers and other related support services providers for Vandenberg AFB reside within the unincorporated areas of Santa Barbara County and in the cities of Lompoc, Santa Maria, Guadalupe, Buellton, Solvang, and Santa Barbara. The key local roads providing access to Vandenberg AFB include SR-1, SR-135, Santa Lucia Canyon Road, SR-246, U.S. 101, and Central Avenue (U.S. Department of the Air Force, 1998a).

Peak-Hour Volumes and existing Level of Service for key roads on Vandenberg AFB are presented in table 3.5.10-1 (U.S. Department of the Air Force, 1998a).

Table 3.5.10-1: Peak-Hour Traffic Volumes and Levels of Service on Key Roads—Vandenberg AFB

</tr>
</tbody>
</table>

On-Site
The major roads on Vandenberg AFB that provide access to the project sites are Coast Road, Bear Creek Road, 13th Street, and Ocean Avenue (figure 3.5.10-1). Coast Road is a two-lane undivided roadway providing access to SLC-6. Coast Road connects to Bear Creek Road, north of SLC-6. Bear Creek Road is a two-lane arterial that provides access to the launch site location SLC-3W. Bear Creek Road is accessible through 13th Street from the north or Ocean Avenue from the east. The Solvang Gate, Santa Maria Gate, and El Rancho Gate are connected to 13th Street, a two-lane arterial that runs north south on the base. Ocean Avenue is an east-west road that bisects Vandenberg AFB and connects with Bear Creek and Coast roads. The Solvang and South Vandenberg AFB gates are located just north and south, respectively, of Ocean Avenue (U.S. Department of the Air Force, 1998a).

Rail Lines
The ROI for railways includes the Southern Pacific, Santa Maria Valley, and the Ventura County Railroad companies, which provide services to the cities of Santa Maria, Lompoc, Santa Barbara, San Luis Obispo, and Ventura. Three branch lines connect Vandenberg AFB to the Southern Pacific Railroad main line. Approximately four passenger trains and eight freight trains pass through Vandenberg AFB daily. The railroad tracks pass between the Pacific Ocean and the launch facilities and must be overflown during launches; however, trains are never overflown during launches due to the potential risk to people and property. An electronic surveillance system, posted railroad schedules, and close coordination, including radio

communication, between train engineers and Vandenberg AFB launch personnel, are used to minimize the possibility of an overflight.

3.5.11 WATER RESOURCES—VANDENBERG AIR FORCE BASE

Appendix B includes a brief overview of water resources and the related federal regulatory framework.

3.5.11.1 Region of Influence

The water resource ROI for the Vandenberg AFB study area includes those freshwater and saltwater resources that could be affected by the construction and operation of launching and support facilities. These resources are within, and adjacent to, the boundaries of Vandenberg AFB and are further described in the next section. The affected environment related to remote telemetry sites is not addressed because activities at these locations would be limited to the use of existing paved and gravel areas. Therefore, the potential for adverse water resource impacts is minimal.

3.5.11.2 Affected Environment

Surface Water and Groundwater Resources

Rainfall at Vandenberg AFB is relatively light, ranging from approximately 29 centimeters (11.5 inches) per year along the coast to about 32 centimeters (12.5 inches) per year further inland near Lompoc (U.S. Department of the Air Force, 1997b). Seven drainages are found in the Vandenberg AFB region, with the major streams being the Santa Ynez River and San Antonio Creek. Smaller streams include Cañada Tortuga, Shuman, Cañada Honda, Bear and Jalama Creeks. These streams and their smaller tributaries drain large areas, with many of the streams only having flows during or shortly after rain storms. Numerous ponds and man-made lakes are found on Vandenberg AFB including MOD III and Pine Canyon Lakes along with Lompoc Casmalia Pond, Joe’s Pond, ABRES-A Lake, and El Rancho Pond (figure 3.5.11-1).

Groundwater in the vicinity of Vandenberg AFB is found in three different groundwater basins. The southern portion of the Vandenberg AFB includes a portion of the Lompoc Terrace Basin and the Lompoc Plain Basin. The San Antonio Creek groundwater basin underlies the northern portion of Vandenberg AFB. Smaller, isolated aquifers are found beneath alluvial fans on the base or in perched aquifers at higher elevations.

Water Quality

Some surface water quality sampling was conducted on the base by the U.S. Air Force in 1991. As reported in the 1998 Final EIS Evolved Expendable Launch Vehicle (U.S. Department of the Air Force, 1998a), this sampling determined that off-base agricultural runoff has led to elevated total dissolved solids, phosphates, and nitrates. Water quality is maintained through adherence to the 30 SW Water Quality Plan, Wastewater Management Plan, and Stormwater Pollution Prevention Plan, all updated in August 2000.

Water Use

The Vandenberg AFB water supply primarily comes from surface water purchased from the California Department of Water Resource’s State Water Project. Four wells that tap the San Antonio Creek groundwater basin are only used as a supplemental supply.

GMD ETR Final EIS
3.6 PEARL HARBOR—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE

The proposed GMD ETR activities could have an effect on air quality, airspace, biological resources, hazardous materials and waste, health and safety, utilities, and visual and aesthetic resources at Pearl Harbor. These resource areas are summarized in the following sections.

By nature of its marine mission and use of existing homeport facilities, SBX support and operational activities would not result in any adverse effects to cultural resources, geology and soils, land use, noise, socioeconomics, transportation, and water resources. Consequently, this section will not include further analysis of these resources other than the summary in the following paragraphs.

Cultural

There are not expected to be any ground disturbing activities within areas where cultural resources are located. While some mooring locations may have traditional importance, such as native fishing grounds, the SBX would occupy a very small area on a temporary basis. The remaining time the area would remain open.

Geology

While potential warehouse and administration facility construction activities could result in limited clearing and excavation for building foundations, it is not expected to create any adverse erosion effects to geology or soils. Construction activities would follow standard guidelines.

Land Use

Land use impact would be minimal since the proposed activities would occur on the water at the pier or near an existing mooring location and would not produce a change in the type of utilization. Land utilization in surrounding areas would not change.

Noise

No sensitive receptors would be disturbed by the proposed intermittent and short-term activity, and noise levels would to be below OSHA workplace standards.

Socioeconomics

As a result of its isolation, limited population, and local economic activity, only minor positive socioeconomic impacts would occur.

Transportation

The few additional personnel would not affect transportation. Shipping of project-related materials, as well as transportation of personnel, would utilize air, roadway, and shipping/ferrying routes that are equipped to handle both the loads and frequency of project demands. Any increase in daily trips by support personnel would utilize existing transportation infrastructure. Shared vehicle and/or off-peak hour travel would further serve to minimize effects on transportation levels.
Water Resources
Impacts to water resources would be negligible, similar to other large marine vessels.

3.6.1 AIR QUALITY—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PEARL HARBOR

3.6.1.1 Region of Influence
The ROI areas that may potentially be affected by the use of Pearl Harbor for the SBX include Pier Victor 3 and the mooring sites as identified in section 2.3.1.6.

3.6.1.2 Affected Environment
Climate
Temperatures in the Pearl Harbor region vary greatly season to season and during a 24-hour period. Highs of 30.5 to 32°C (87 to 89°F) are not unusual during midsummer afternoons, while temperatures of 22 to 24°C (72 to 76°F) are typical night temperatures during the same season. Winter and early spring temperatures range from 22 to 26°C (76 to 78°F) during the day to the mid-teens °C (low 60's °F) during the evenings. Relative humidity varies between lows of 58 to 60 percent to highs of over 80 percent.

Rainfall is typically light. However, occasional heavy rains can be caused by times of southerly winds. Monthly median peak rainfall occurs between November and February, with the lowest occurring between March and September. The mean annual rainfall for the region lies between 100 to 230 centimeters (40 to 90 inches) per year.

Prevalent for approximately nine months of the year, the prevailing winds tend to be northeast tradewinds. The remainder of the year sees south to southwest winds and mild offshore breezes prevailing. Winds up to 64 kilometers per hour (40 miles per hour) may occasionally strike from the north or northeast, but seldom reach gale velocities. (Department of the Navy Pacific Missile Range Facility, Hawaii, 2001)

Regional Air Quality
The state of Hawaii is in attainment of the NAAQS established for carbon monoxide, nitrogen dioxide, sulfur dioxide, particulate matters, ozone, and lead. (State of Hawaii Department of Health, Clean Air Branch, 2001)

Existing Emissions
According to the 2001 Annual Summary of Hawaii Air Quality Data, the entire state of Hawaii is in attainment. Table 3.6.1-1 lists the emissions recorded at two points near Barbers Point; West Beach, which is approximately 43 kilometers (27 miles) west of downtown Honolulu and Kapolei, approximately 40 kilometers (25 miles) west of downtown Honolulu. All levels recorded were well within the NAAQS and state AAQS. (State of Hawaii Department of Health, Clean Air Branch, 2001)

3.6.2 AIRSPACE—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PEARL HARBOR

Appendix B includes a general description of airspace.

3.6.2.1 Region of Influence

The ROI for airspace at Pearl Harbor includes the airspace over and surrounding the potential SBX interference areas that extend from the mooring location off the coast of Barbers Point, Hawaii (figure 3.6.2-1).

3.6.2.2 Affected Environment

Controlled and Uncontrolled Airspace

The Honolulu ARTCC regulates air traffic in the Hawaiian Islands. Class B airspace is in effect at Honolulu International Airport and above the Kalaeloa (Rodgers) Airport. Class D airspace surrounds the Kalaeola Airport.

Special Use Airspace

Special use airspace is located north of the ROI (Schofield—Makua and Wheeler AFB restricted areas) and south of the ROI (Warning Areas W192 and W193).
Airspace Over the Potential SBX Mooring Area at Barbers Point, Hawaii

Oahu, Hawaii

Figure 3.6.2-1

En Route Airways and Jet Routes

Several low altitude airways are located within the ROI. V15 and V12 are in the north central part of the ROI, V4 crosses through the missile of the ROI, and V16 crosses the southern portion of the ROI. V2, V20, and V21 are located on the eastern edge of the ROI.

Airports/Airfields

Airports include Honolulu International, Kalaeloa (Rodgers) Airport, and Wheeler Army Airfield.

3.6.3 BIOLOGICAL RESOURCES—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PEARL HARBOR

Appendix B contains a general description of biological resources and the main regulations and laws that govern their protection.

3.6.3.1 Region of Influence

The ROI includes areas that may potentially be affected by the use of Pearl Harbor for the SBX, including Pier Victor 3 and the mooring sites as identified in section 2.3.1.6.

3.6.3.2 Affected Environment

Terrestrial biological resources are not addressed since those areas (Pier Victor 3) where elements of the Proposed Action would take place onshore are already developed and disturbed.

Nine marine wildlife species listed as federal and state threatened or endangered species are known or suspected to occur in Hawaiian waters. These species, which are listed in table 3.4.2-1, include the Hawaiian monk seal, whales, and sea turtles. More than 20 species of dolphins and toothed whales are known to exist around the islands. On Oahu, whales are normally sighted consistently beginning in January, and are moderately abundant in adjacent waters until April (Hawaii State Department of Transportation, Harbors Division, 2001). Coral coverage in the area ranges from 80 to 90 percent at depths between 18 and 24 meters (58 and 78 feet) to less than 1 percent in water depths from 24 to 36 meters (78 to 120 feet). Lobe corals, cauliflower corals, and finger corals dominate the coral community. Diverse and abundant fish species are associated with areas greater than 40 meters (120 feet) in depth with vertical relief that contain coral coverage. Fifty-nine species of fish have been identified in the vicinity of Barbers Point. The most common species include sturgeon fish, butterfly fish, damselfish, wrass, and triggerfish. A commercial net pen cage aquaculture site is located north of the proposed site. (U.S. Department of the Navy, 2002a)

Of the 18 whale pods observed during recent surveys associated with proposed Kalaeloa Barbers Point Harbor, 12, or 67 percent, were seen near Barbers Point. The two species of cetaceans most frequently observed during daytime surveys are humpback whales and spinner dolphins. (Hawaii State Department of Transportation, Harbors Division, 2001)
3.6.4 HAZARDOUS MATERIALS AND HAZARDOUS WASTE—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PEARL HARBOR

3.6.4.1 Region of Influence
The ROI for hazardous materials and hazardous waste includes those areas that may potentially be affected by the proposed deployment of the SBX to Pearl Harbor. The ROI includes fueling areas, support and maintenance operations and waste storage and disposal. Appendix B includes a detailed discussion of maritime and other laws, regulations and standards concerning hazardous materials and hazardous waste.

3.6.4.2 Affected Environment
The Coast Guard 14th District Marine Safety Office (MSO) Honolulu is responsible for the enforcement of hazardous material and hazardous waste regulations and policies for navigable waterways and adjoining shorelines and for response to spills and releases. An Area Committee composed of industry, federal, state, and local regulatory representatives serves as a regional spill preparedness and planning group. In compliance with the National Contingency Plan (40 CFR Part 300) and the Oil Pollution Act of 1990, the Committee, with assistance and oversight from the Coast Guard, developed an Area Contingency Plan outlining regional spill response procedures.

Shipboard Hazardous Materials Management
Environmental compliance policies and procedures applicable to shipboard operations are defined in OPNAVINST 5090.1B (1999), Chapter 19. These instructions reinforce the Clean Water Act’s prohibition against discharge of harmful quantities of hazardous substances into or upon U.S. waters out to 370 kilometers (200 nautical miles). Navy ships are required to conduct operations at sea in such a manner as to minimize or eliminate any adverse impacts on the marine environment. This includes stringent hazardous waste discharge, storage, dumping, and pollution prevention requirements. Table 3.6.4-1 summarizes pollution control discharge restrictions for U.S. Navy vessels at sea.

**Hazardous Materials**

| U.S. Waters (0 to 5.5 kilometers [0 to 3 nautical miles]) | No discharge | No discharge |
| U.S. Contiguous Zone (5.5 to 22 kilometers [3 to 12 nautical miles]) | No discharge | No discharge |
| 22 to 46.3 kilometers (12 to 25 nautical miles) from shore | No discharge | No discharge |
| >46.3 kilometers (25 nautical miles) from shore | No discharge | No discharge |
| >92.6 kilometers (50 nautical miles) from shore | No discharge | If health and safety is threatened, discharge of negatively buoyant sterilized waste packages is permitted |
| >370.4 kilometers (200 nautical miles) from shore | Discharge permitted under certain circumstances; however, to the maximum extent practicable, ships shall retain hazardous materials onboard for shore disposal | Same as Hazardous Materials restrictions |

Source: Department of the Navy, Office of the Chief of Naval Operations, 1999.
Hazardous Waste Management
Hazardous waste and nonhazardous waste generated during routine operations at Pearl Harbor may include contaminated jet fuel, waste rags, paint, spent solvents, spill residues and absorbent materials, corrosion prevention compound in aerosol cans, ethylene glycol, batteries, antifreeze, hydraulic fluid, waste oil, photo processing waste materials, cleaning compounds, spill cleanup materials, and empty containers.

Naval Station Pearl Harbor Victor Pier 3
Hazardous material use and disposal are managed in such a way as to minimize impacts to the environment.

Barbers Point Mooring Location
The mooring location is located approximately 5 kilometers (3 miles) south of Barbers Point. Barbers Point Deep Draft Harbor is one of three commercial harbors on the island of Oahu and the State’s second busiest harbor. The approximately 37-hectare (92-acre) inshore harbor basin includes ship berthing areas, an approximately 12-hectare (30-acre) cargo handling yard, a 488-meter (1,600-foot) pier and petroleum product pipelines. Containment booms are located on site. Initial spill/emergency response equipment is stored at Tesoro Hawaii Corporation with additional equipment available from Honolulu Harbor. (U.S. Coast Guard, Marine Safety Office, Honolulu, 2002)

An explosive anchorage is located east/southeast of Barbers Point, approximately 2.4 kilometers (1.5 miles) from the Kalihi Channel along the 11-fathom line.

3.6.5 HEALTH AND SAFETY—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PEARL HARBOR

3.6.5.1 Region of Influence
The ROI for health and safety includes those areas that may potentially be affected by the proposed deployment of the SBX to Pearl Harbor. The ROI for health and safety is based on the area where effects to human exposure, navigation and communication facilities/equipment (military and nonmilitary), fuels and any existing EMR at Pearl Harbor may occur by the use of an XBR. Table 2.1.4-2 lists the maximum potential interference distances that define the ROI based on various subjects that could interact with the radar. Appendix B includes a general description of the health and safety resource area and a detailed discussion of the laws, regulations and standards concerning maritime safety and EMR.

3.6.5.2 Affected Environment
Regional
The Coast Guard enforces marine safety regulations implemented to reduce or eliminate death, injury, economic loss, and environmental damage associated with commercial marine and military vessels. MSO responsibilities include inspecting commercial vessels and marine facilities, supervising the transfer of oil, hazardous materials and explosive and military cargoes, investigating and remediating oil spills and hazardous materials releases, investigating vessel casualties and licensing of merchant vessels.
Coast Guard/MSO areas of responsibility include the following safety and operating areas:

- Oahu’s Anchorage Grounds, as defined and listed in 33 CFR Parts 110.235, 110.236 and 110.237, including Barbers Point Deep Draft Harbor and Offshore of Barbers Point. Nonanchorage Areas have also been established offshore of Barbers Point to protect submerged pipelines.
- Pearl Harbor Naval Defensive Sea Area as established by Executive Order 8681 in 1941. MSO coordinates with the military Commanding Officer who is given authority, as defined by 33 CFR Part 761.7(a)(1), to control boating activity in the Naval Defensive Sea Area.
- Oahu’s Restricted Areas and Danger Zones, as defined and listed in 33 CFR Parts 334.1340 to 334.1400 and 334.1410, to protect public from hazardous activities occurring in designated areas such as weapons training and missile launches.
- Submerged Submarine Operating Areas off the southwest coast of Oahu, off of Diamond Head Crater and Ala Moana Beach Park.
- Navy Small Arms Firing Area located west of the entrance channel to Pearl Harbor.
- Temporary Safety, Permanent Safety and Security Zones – Subsequent to 11 September 2001, the Coast Guard established temporary security zones in designated waters adjacent to the islands of Oahu, Maui, Hawaii, and Kauai, Hawaii. These security zones extend from the surface of the water to the ocean floor and were determined necessary by the Coast Guard to protect personnel, vessels and facilities from acts of sabotage or other subversive acts, accidents, or other causes of a similar nature during port and waterway operations.
- The Kaiwi Channel Voluntary Tanker Avoidance Zone established in response to OPA 90 to reduce the potential of a worst-case oil spill disaster. The maritime industry has voluntarily agreed that all tankers will use the Kauai Channel.

MSO facilitated the establishment of the Hawaii Operational Safety Team (HOST) in 1997. HOST is a non-regulatory group represented by the marine industry, public, state and federal agencies concerned with operational safety in the state’s ports and waterways. HOST has developed SOPs for vessel maintenance and repair, voluntary commercial towing vessel examinations, minimal under-keel clearance (in commercial ports), commercial VHF/FM communication procedures, explosive handling in Oahu ports, and Submerged Submarine Operating Areas (Diamond Head Crater and Ala Moana Beach Park), among others. Once approved, SOPs are listed in the HOST Handbook and posted on the MSO website.

The Coast Guard is also responsible for developing and issuing local NOTMARs.

The World-Wide Navigational Warning Service also provides long range and coastal warning messages as well as special warnings of potential political or military hazards that may affect safety of U.S. shipping lanes to U.S. Navy and merchant ships through a worldwide radio and satellite broadcast system.

The Navy, Barbers Point Deep Draft Harbor, Offshore Barbers Point, and tenants of Campbell Industrial Park have entered into a mutual aid agreement to provide assistance, equipment and manpower, in the event of fire or other emergencies (U.S. Coast Guard, Marine Safety Office, Honolulu, 2002).
Pier Victor 3 and Barbers Point
A Navy point of contact outlines the guidelines for safety procedures at Pearl Harbor.

Electromagnetic Radiation Environment
Radiation is regulated under 11 Hawaii Administrative Rules 41, 42, 44, and 45.

Communications—Electronics Frequency Related Interference. Section 3.6.2 provides an overview of the airspace and airports in the Pier Victor 3 and Barbers Point ROI.

3.6.6 UTILITIES—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PEARL HARBOR

3.6.6.1 Region of Influence
The ROI areas that may potentially be affected by the use of Pearl Harbor for the SBX include Pier Victor 3 and the potential mooring locations as previously identified off Barbers Point.

3.6.6.2 Affected Environment
At Pearl Harbor, the Utilities Department provides electricity, potable water distribution and wastewater collection/treatment as well as steam, salt water, boiler feedwater and compressed air. It also offers operating, maintenance and repair services for customer-owned utility systems on a cost-reimbursable basis. In addition, the department provides ship services which connect utilities systems to ships berthed at Pearl Harbor piers. (Navy Public Works Center, Pearl Harbor, 2002b)

Energy
The Utilities Department provides electricity at Pearl Harbor. Although there is no shore power (dock outlets), power lines run near Pier Victor 3, allowing for relatively easy modifications to provide the platform with power. Power is typically provided by linking to nearby buildings; however, tying a temporary transformer into a primary line is another option (Noborikawa, 2002).

Water
The Utilities Department provides potable water as well as salt water. Pier Victor 3, on Pearl City Peninsula, is currently supplied with potable water via a 15-centimeter (6-inch) water line (Noborikawa, 2002).

Wastewater
The Utilities Department provides wastewater collection/treatment. Additionally, the department services such as the Ship Wastewater Collection Ashore Abatement System (Navy Public Works Center, Pearl Harbor, 2002b). The Bilge Water Branch of Environmental Services provides treatment/disposal of bilge water (with less than 5 percent oil) from ships and submarines. Currently, the waste is collected by tank trucks, but an ongoing construction project will allow ships to discharge directly into risers at the pier. (Navy Public Works Center, Pearl Harbor, 2002a) Current regulations prevent running a wastewater line at Pier Victor 3,
due to the possibility of cross-contamination (Noborikawa, 2002), and wastewater at the pier would be containerized, requiring that arrangements be made for disposal.

**Solid Waste**

Solid wastes are handled by the Solid Waste Branch of the Navy Public Works Center. It operates a biosolids (sewage sludge) composting facility which converts military-generated sewage sludge and green waste into a reusable topsoil; the branch also remediates petroleum-contaminated soil and oily waste (Navy Public Works Center, Pearl Harbor, 2002a). The industrial waste facility treats a variety of hazardous and nonhazardous liquids (Navy Public Works Center, Pearl Harbor, 2002a).

3.6.7 **VISUAL AND AESTHETIC RESOURCES—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PEARL HARBOR**

Appendix B includes a description of visual and aesthetic resources and the analysis of the potential impacts from the Proposed Action.

3.6.7.1 **Region of Influence**

The Proposed site is offshore of Barbers Point near Pearl Harbor on the island of Oahu in Hawaii. The ROI for visual and aesthetic resources includes the beach at Barbers Point, which consists of the James Campbell Industrial Park, Kalaeloa (Rodgers) Airport, and state- and city-maintained land.

3.6.7.2 **Affected Environment**

Primarily, Barbers Point is occupied by the James Campbell Industrial Park, which consists of several industrial corporations along with Hawaii State- and Honolulu City-owned properties. The industrial park consists of conventional industrial buildings including smokestacks, office areas, parking lots, etc. The state- and city-owned properties are typically sandy beaches sparsely vegetated with tropical flora and primarily used for recreational purposes. The area also includes a lighthouse. The remainder of Barbers Point consists of the Kalaeloa (Rodgers) Airport, the Barbers Point Beach Park, and a small area owned and maintained by the State of Hawaii. This area also consists of several resorts and golf courses.

The ocean area adjacent to Barbers Point generally has a sea state of 3 to 4, small waves with frequent whitecaps to larger than moderate waves with many whitecaps. This area is primarily used as a recreation site for surfing, fishing, swimming, and other beach activities.

The ROI is frequented by workers from the industrial park, boaters, surfers, fishermen, and other beachgoers. Visitors that would be considered sensitive among these groups would be tourists and other recreational visitors, as well as everyday users.
3.7 NBVC PORT HUENEME—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE

The proposed GMD ETR activities could have an effect on air quality, airspace, biological resources, hazardous materials and waste, health and safety, and utilities at Port Hueneme. These resource areas are summarized in the following sections.

By nature of its marine mission and use of existing homeport facilities, SBX support and operational activities will not result in any adverse effects to cultural resources, geology and soils, land use, noise, socioeconomics, transportation, visual and aesthetic resources, and water resources. Consequently, this section will not include further analysis of these resources other than the summary in the following paragraphs.

Cultural
There are not expected to be any ground disturbing activities within areas where cultural resources are located. While some mooring locations may have traditional importance, such as native fishing grounds, the SBX would occupy a very small area on a temporary basis.

Geology
While potential warehouse and administration facility construction activities could result in limited clearing and excavation for building foundations, it is not expected to create any adverse erosion effects to geology or soils. Construction activities would follow standard guidelines.

Land Use
Land use impact would be minimal since the proposed activities would occur on the water at the pier or near an existing mooring location and would not produce a change in the type of utilization. Land utilization in surrounding areas would not change.

Noise
No sensitive receptors would be disturbed by the proposed intermittent and short-term activity, and noise levels would to be below OSHA workplace standards.

Socioeconomics
As a result of its isolation, limited population, and local economic activity, only minor positive socioeconomic impacts would occur.

Transportation
The few additional personnel would not affect transportation. Shipping of project-related materials, as well as transportation of personnel, would utilize air, roadway, and shipping/ferrying routes that are equipped to handle both the loads and frequency of project demands. Any increase in daily trips by support personnel would utilize existing transportation infrastructure. Shared vehicle and/or off-peak hour travel would further serve to minimize effects on transportation levels.
**Visual and Aesthetic Resources**

No effects to visual and aesthetic resources are expected. San Nicolas Island is a military installation and while the visual resources on San Nicolas may be considered significant by some viewers, the proposed action is consistent with that of a military installation. The proposed site is approximately 105 kilometers (65 miles) from the affected population and would not be visible from Port Hueneme.

**Water Resources**

Impacts to water resources would be negligible, similar to other large marine vessels.

### 3.7.1 AIR QUALITY—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, NBVC PORT HUENEME

#### 3.7.1.1 Region of Influence

The ROI includes areas that may potentially be affected by the use of NBVC Port Hueneme/San Nicolas Island for the SBX, including the mooring sites identified in section 2.3.1.7.

#### 3.7.1.2 Affected Environment

**Climate**

NBVC Port Hueneme and San Nicolas Island are located in Ventura County, which is located within the South Central Coast Air Basin. The area experiences the mild Mediterranean climate typical of southern California. For NBVC Port Hueneme temperatures are moderate with average daily summer highs of 21°C (70°F) and average daily winter lows of 4°C (40°F). Most precipitation occurs during the months of November through April, with average annual rainfall ranging from 25 to 46 centimeters (10 to 18 inches) along the coast. Along the coast, prevailing winds come from the west/northwest during the day at about 11 to 19 kilometers (7 to 12 miles) per hour. While evening winds stem from the east.

On San Nicolas Island total annual precipitation averages 21.3 centimeters (8.4 inches). The dry season occurs between May and September, with the rainy season November to March. During the rainy season the island receives about 87 percent of its rainfall. The average mean monthly temperature on land is 15°C (59°F). Prevailing winds tend to come from the northwest, at an average speed of 24.1 kilometers (13.3 miles) per hour. (Department of the Navy, Naval Air Warfare Center, Weapons Division, 2002)

**Regional Air Quality**

Ventura County is considered to be a severe nonattainment area for federal and state 1-hour ozone standards. And while ozone levels have been declining significantly in recent years, the county as a whole still experiences frequent violations of the federal and state ozone standards. Inland areas tend to exceed ozone stands more frequently than the coast areas. Ventura County is also considered to be in nonattainment for the state standard for PM-10. Ambient levels of other pollutants in Ventura County do not violate state or federal standards. (Ventura County Air Pollution Control District, Air Quality Planning and Evaluation Division, 2000)
San Nicolas Island is considered to be in attainment/unclassifiable as to air quality by the EPA. (Department of the Navy, Naval Air Warfare Center, Weapons Division, 2002)

**Existing Emission Sources**

San Nicolas Island is considered to be part of the Point Mugu Sea Range, and within the Sea Range emission sources include aircraft operations, missile and target operations, and marine vessel operations. Table 3.7.1-1 lists a summary of Sea Range Emissions at San Nicolas Island.

### Table 3.7.1-1: Summary of San Nicolas Island Emissions

3.7.2 AIRSPACE—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, NBVC PORT HUENEME

Appendix B includes a general description of airspace.

3.7.2.1 Region of Influence

The ROI for airspace at NBVC Port Hueneme includes the airspace over and surrounding the potential SBX interference areas at San Nicolas Island (figure 3.7.2-1).

3.7.2.2 Affected Environment

Controlled and Uncontrolled Airspace

San Nicolas Island is located in international airspace. Therefore, the procedures of the ICAO (outlined in ICAO Document 444, Rules of the Air and Air Traffic Services) are followed (International Civil Aviation Organization, 1996; 1997). The ICAO is a specialized agency of the United Nations whose objective is to develop the principles and techniques of international air navigation and to foster planning and development of international civil air transport. The FAA acts as the U.S. agent for aeronautical information to the ICAO, and air traffic in the ROI is managed by the Los Angeles ARTCC.

Special Use Airspace

The airspace over San Nicolas Island is within the Point Mugu Sea Range, which is controlled by NAWCWD. When the Sea Range is not being used, NAWCWD turns over the airspace to the FAA. (NAVAIR) The Point Mugu Sea Range includes warning areas and restricted airspace R-2535 A and B above San Nicolas Island.

En Route Airways and Jet Routes

Aircraft operating on Instrument Flight Rules (IFR) clearances under control of the Los Angeles ARTCC normally fly on formal airway route structures. In the vicinity of NBVC Port Hueneme,

Port Hueneme, California

Airspace Over the Potential SBX Mooring Area at San Nicolas Island

Figure 3.7.2-1

GMD ETR Final EIS
these airways run along the coastline and to the east. Special airways, Control Area Extensions (CAEs), cross the Point Mugu Sea Range to the west and can be opened or closed by the FAA at the request of the Navy in order to facilitate activities on the Sea Range. One CAE, 1177, is located south of San Nicolas Island, along the southern border of the Point Mugu Sea Range. CAE 1177 is the most important of the CAEs in the ROI and is rarely closed. Two other CAEs, 1316 and 1318, are located north of San Nicolas Island.

CAEs 1316 and 1318 are closed daily during daylight hours and occasionally on weekends. The FAA does not record the numbers of IFR flights through the Sea Range on the CAEs. However, general estimates of traffic through the Sea Range on all the CAEs are about 20 arrivals and departures daily. This is only IFR traffic and does not include aircraft flying under Visual Flight Rules (VFR).

Memoranda of Agreement exist between NAWCWD and the FAA which address the usage of the Warning Areas and stipulate the conditions under which the CAEs can be closed to civil traffic. Under most circumstances at least one CAE must remain available for use by general aviation and commercial air carriers. NAWCWD has established procedures to minimize the disruption of other air traffic due to operations on the range.

Since most of the Sea Range is over international waters, aircraft operate under VFR or without clearance from Air Traffic Control. Flight under these conditions is conducted under a see-and-avoid concept and flown clear of clouds or other limited-visibility conditions such as rain or fog.

**Airports/Airfields**

There is a runway on San Nicolas Island. Other runways in the ROI include Naval Air Station (NAS) Point Mugu, Oxnard, Camarillo, and Santa Barbara Municipal.

### 3.7.3 BIOLOGICAL RESOURCES—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, NBVC PORT HUENEME

Appendix B contains a general description of biological resources and the main regulations and laws that govern their protection.

#### 3.7.3.1 Region of Influence

The ROI includes areas that may potentially be affected by the use of NBVC Port Hueneme/San Nicolas Island for the SBX, including the mooring sites identified in section 2.3.1.7.

#### 3.7.3.2 Affected Environment

Most common southern California seabirds and shorebirds nest or are seasonally present on San Nicolas Island. Western gull, Brandt’s cormorant, double-crested cormorant, western sandpiper, Pacific golden plover, and sooty shearwater are examples of these species. Resident and migratory terrestrial species include the American kestrel, horned lark, rock wren, and house finch. (U.S. Army Space and Strategic Defense Command, 1994)
The Point Mugu Sea Range includes the ocean depths out to 322 kilometers (200 miles), an area including the water offshore of NBVC Port Hueneme and the shallow waters around the Channel Islands. Threatened and endangered species in the water offshore of NBVC Port Hueneme include blue, fin, sei, humpback, sperm, and northern right whales and the southern sea otter. The gray whale migrates from December through April south along the California coast including the area offshore of NBVC Port Hueneme. The waters surrounding San Nicolas Island support species of seals and whales. Approximately 75 percent of the sea lions and seals that inhabit southern California spend some portion of time in the northern Channel Islands. A small number of federally threatened Guadalupe fur seals (*Arctocephalus townsendi*) have been observed on San Nicolas Island (National Marine Fisheries Service, 2002). San Nicolas Island contains significant breeding populations of California sea lions and northern elephant seals. The principal breeding grounds for these species are on the southern and western shoreline of the island. California sea lions can be found throughout the year on Southern California offshore islands, with yearly peaks in summer (breeding). The breeding period for the northern elephant seal is from December to March. Harbor seals, which breed in September, also occur on the island. Killer whales are seen occasionally around the Channel Islands, predominantly during the gray whale migration. The federally threatened sea otter also occurs in the area. The Channel Islands National Marine Sanctuary is discussed above under the environmentally sensitive habitat of Vandenberg AFB. (U.S. Army Space and Strategic Defense Command, 1994)

3.7.4 HAZARDOUS MATERIALS AND HAZARDOUS WASTE—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, NBVC PORT HUENEME

3.7.4.1 Region of Influence

The ROI for hazardous materials and hazardous waste includes those areas that may potentially be affected by the proposed deployment and use of the SBX to NBVC Port Hueneme/San Nicolas Island for the SBX. The ROI includes fueling areas, support and maintenance operations and waste storage and disposal.

3.7.4.2 Affected Environment

**Hazardous Materials Management**

Hazardous materials are transported to San Nicolas Island by barge or aircraft from NAS Point Mugu. The largest volume of hazardous material transported to and stored at San Nicolas is aviation jet fuel and unleaded gasoline. Approximately 680,000 gallons (2.6 million liters) of jet fuel and 52,000 gallons (198,000 liters) of unleaded gasoline are shipped to San Nicolas yearly. The unleaded gasoline is primarily used by ground vehicles. Various other hazardous materials such as oils and hydraulic fuels are also used to support maintenance of aircraft and vehicles. Minimal quantities of maintenance support materials are ordered and stored in order to reduce risk of leaks/spills and prevent disposal of excess material or waste.

**Hazardous Waste Management**

There are eight satellite hazardous waste storage areas on San Nicolas. Hazardous wastes are stored at these satellite accumulation areas prior to being transported to the less-than-90-day accumulation area on the Island. From the less than 90-day accumulation area, the waste is shipped by barge to Port Hueneme. After arrival at Port Hueneme, the waste is transported to an approved Treatment, Storage, and Disposal facility. Approximately 65,689 pounds (29,813 kilograms) of hazardous waste are shipped yearly from San Nicolas to Port Hueneme.
3.7.5 HEALTH AND SAFETY—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, NBVC PORT HUENEME

3.7.5.1 Region of Influence

The ROI for health and safety includes those areas that may potentially be affected by the proposed deployment and use of the SBX to NBVC Port Hueneme/San Nicolas Island. The ROI for health and safety is based on the area where effects to human exposure, navigation and communication facilities/equipment (military and nonmilitary), fuels and any existing EMR at San Nicolas Island may occur by the use of an XBR. Table 2.1.4-2 lists the maximum potential interference distances that define the ROI based on various subjects that could interact with the radar. Appendix B includes a general description of the health and safety resource area and a detailed discussion of the laws, regulations, and standards concerning maritime safety and EMR.

3.7.5.2 Affected Environment

Electromagnetic Radiation

The U.S. Navy operates a variety of equipment and facilities, including radar, communication facilities, and power utility lines, at San Nicolas Island which generate EMR. The on-base hazards of EMR to personnel (HERP), ordnance (HERO), and fuel (HERF) have been determined using information supplied by the NAS Point Mugu Weapons Department. HERF constraints are considered to be negligible and are not depicted. The HERO arcs are large enough to extend beyond base boundaries; however, these arcs only affect ordnance on-base, and strict EMR control procedures are used when HERO-susceptible ordnance is transported or present in the open.

Explosive Safety Quantity–Distance Arcs

Various munitions and targets are stored and maintained at San Nicolas Island that are susceptible to the effects of EMR. These include missile warheads, rocket motors, high explosives and other similar type ordnances which are used in testing or training activities occurring on the Sea Range. Munitions arrive on the Island either by surface ship or by air transport. ESQD arcs for the safety of personnel and equipment have been established around the munitions storage and assembly areas.

Section 3.7.2 provides an overview of the airspace in the NBVC Port Hueneme/San Nicolas Island ROI.

Sea Range

The Sea Range safety policy, procedures, and guidance are covered in NAWCWD Instruction 5100.2 dated 9 July 1993. The safety policy of NAWCWD is to observe every reasonable precaution in the planning and execution of all operations which occur on the Sea Range to prevent injury to people and damage to property. Although the Commander of NAWCWD has the ultimate responsibility for range safety, the authority for execution of these safety programs is delegated to the Sea Range Safety Officer in the Range Safety Office.

Access to San Nicolas Island is strictly controlled and limited to pre-approved military personnel or non-military personnel conducting scientific studies. A scheduled contract aircraft shuttle operates between NAS Point Magu and San Nicolas.
There are three surface restricted areas located around San Nicolas Island and two airspace restricted areas over San Nicolas. Section 3.7.2 provides an overview of the airspace in the NBVC Port Hueneme/San Nicolas Island ROI.

NAWCWD has an extensive surveillance system to implement real-time safety clearance procedures prior to initiation of any operation on the sea range. This system includes the use of land-, sea-, and air-based radar in addition to aircraft surveillance of the range which is necessary to ensure that the public remains clear of designated operational areas where they could be subjected to hazardous conditions. The range uses specially modified P-3 aircraft, the NP-3D, which provides extended Sea Range surveillance. A review of past Range Safety Office records show that accidents involving the public on the Sea Range have never occurred.

When the Sea Range is used for military testing and training operations, the Navy notifies commercial, civilian, and other military aviation through a NOTAM which provides appropriate information to the FAA and its Air Traffic Control agencies to route traffic around these Warning Areas and Restricted Areas when they are active. (Warning Areas are located over non-Territorial Waters of the United States; Restricted Areas are located over land or Territorial Waters.) Although a NOTAM does not preclude uncontrolled air traffic from entering a Warning Area even when the area is active, DoD Directive 4540.1, Use of Airspace by U.S. Military Aircraft and Firings Over the High Seas, provides guidance for operating within Warning Areas: non-participating aircraft are identified by radar, and contact with these aircraft is made by radio; if aircraft remain in a clearance area, even after being requested to leave, the Sea Range will delay, cancel, or move a test to a clear area.

Similar procedures exist for notification of the commercial shipping and recreational boating communities of potentially hazardous activities on the Sea Range. These notifications are made through NOTMAR and daily VHF-FM Marine Radio (Channel 16) broadcasts. The Sea Range has established procedures to ensure that non-participating surface vessels are not exposed to undue risk. The surveillance aircraft survey designated clearance areas to ensure that surface vessels are not present. Any vessels, if present, are warned that they are in an area of an impending hazardous activity and are requested to leave the area. Contact with vessels is made by marine band FM radio; however, loud speakers can be used if the boat is not radio-equipped.

### 3.7.6 UTILITIES—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, NBVC PORT HUENEME

#### 3.7.6.1 Region of Influence

The ROI includes areas that may potentially be affected by the use of NBVC Port Hueneme/San Nicolas Island for the SBX, including the mooring sites identified in chapter 2.0, and the area of potential construction of an environmentally controlled warehouse. This site has not been determined.

#### 3.7.6.2 Affected Environment

**Energy**

The Southern California Edison Company provides NBVC Port Hueneme with electricity via a system with a 44,000-kW capacity. The Edison Company has indicated that it would be able to
provide an additional 4.5 million kW with no infrastructure-related costs being passed on to the Navy, allowing for readily available future expansion (Department of the Navy, Naval Air Warfare Center, Weapons Division, 2002).

Currently, San Nicolas Island has the capability to produce approximately 1 MW of electrical power capacity from its own generators. There is limited capacity to support additional personnel, and then only on a limited basis. San Nicolas Island also has a fuel pier available for barge-supported refueling operations.

**Water**

The primary source of potable water for NBVC Port Hueneme is treated groundwater from the Oxnard-Hueneme Water Delivery System under the auspices of the United Water Conservation District in Port Hueneme (United Water Conservation District, 2002). Source water is conveyed through the Oxnard-Hueneme Pipeline (Pringle, 2003) to the Port Hueneme Water Agency Brackish Water Reclamation Treatment Plant. To meet demands, the treated water is then blended with State Water Project water delivered by the Calleguas Municipal Water District (Pringle, 2003). The existing system has a capacity of 22.0 million liters (5.8 million gallons) per day, with an average demand of 20.06 million liters (5.3 million gallons) per day (Department of the Navy, Naval Air Warfare Center, Weapons Division, 2002) overall, and a current demand for NBVC Port Hueneme and NBVC Point Mugu of 6.1 million liters (1.6 million gallons) per day (Pringle, 2003).

**Wastewater**

The City of Oxnard sanitary sewer system serves NBVC Port Hueneme, its collection system conveying the flow to the Oxnard Wastewater Treatment Plant in the southwestern portion of the city. This plant has an average dry weather flow of 120 million liters (31.7 million gallons) per day and an ultimate design capacity of 150.3 million liters (39.7 million gallons) per day (City of Oxnard, 2003).

**Solid Waste**

Solid waste from NBVC Port Hueneme and surrounding communities is collected by a private contractor and taken to an offbase transfer station before being delivered to a landfill. Solid waste from the base is taken to a transfer station in Oxnard and then transported to the 65-hectare (161-acre) Toland Road Landfill, some 24 kilometers (15 miles) from base. Operated by the Ventura Regional Sanitation District, it is expected that this landfill will operate for another 30 years at the present rate of waste generation. The remaining capacity is 4 million cubic meters (30 million cubic yards).
3.8 NAVAL STATION EVERETT—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE

The proposed GMD ETR activities could have an effect on air quality, airspace, biological resources, hazardous materials and waste, health and safety, transportation, utilities, and visual and aesthetic resources at Naval Station Everett. These resource areas are summarized in the following sections.

By nature of its marine mission and use of existing homeport facilities, SBX support and operational activities will not result in any adverse effects to cultural resources, geology and soils, land use, noise, and water resources. Consequently, this section will not include further analysis of these resources, other than the summary in the following paragraphs.

Cultural
There are not expected to be any ground disturbing activities within areas where cultural resources are located. The SBX would be located at Pier Alpha or Pier Bravo.

Geology
While potential warehouse and administration facility construction activities could result in limited clearing and excavation for building foundations, it is not expected to create any adverse erosion effects to geology or soils. Construction activities would follow standard guidelines.

Land Use
Land use impact would be minimal since the proposed activities would occur on the water at the pier location and would not produce a change in the type of land utilization in the immediate or surrounding areas. Land utilization in surrounding areas would not change.

Noise
No sensitive receptors would be disturbed by the proposed intermittent and short-term activity, and noise levels would be below OSHA workplace standards.

Water Resources
Impacts to water resources would be negligible, similar to other large marine vessels.

3.8.1 AIR QUALITY—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, NAVAL STATION EVERETT

3.8.1.1 Region of Influence
The ROI includes areas that may potentially be affected by the use of Naval Station Everett for the SBX, as identified in section 2.3.1.8.
3.8.1.2 Affected Environment

Climate
Climate at Naval Station Everett can be described as cool marine. Average annual rainfall is about 89 centimeters (35 inches). July and August are the driest months, while December and January are the wettest. Temperatures typically range from 15°C (59°F) to 6.7°C (44°F). Summer is the sunniest season and July is the hottest month with an average high of 24°C (75°F). January tends to be the coldest month with lows averaging 1°C (34°F). Prevailing winds during the summer are typically from the north, while winter winds generally come from the south.

Regional Air Quality
Snohomish County falls under the Puget Sound Clean Air Agency’s jurisdiction. The area was previously designated as nonattainment for ozone and carbon monoxide. In recent years however, Snohomish County has met air quality standards and has also established a 10-year plan for continuing to meet and maintain air quality standards. With this, Snohomish County was redesignated to an attainment area and is now referred to as a maintenance area for both ozone and carbon monoxide. (Puget Sound Clean Air Agency, 1998)

Existing Emissions
The Washington Department of Ecology and the Puget Sound Clean Air Agency maintain a network of air quality and meteorological monitoring stations throughout the Puget Sound region, including Everett, Marysville, Getchell, and Lake Sammamish. Table 3.8.1-1 lists the maximum measured concentrations around Naval Station Everett.

3.8.2 AIRSPACE—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, NAVAL STATION EVERETT

Appendix B includes a general description of airspace.

3.8.2.1 Region of Influence
The ROI for airspace at Naval Station Everett includes the airspace over and surrounding the potential SBX interference areas at Naval Station Everett (figure 3.8.2-1).
3.8.2.2 Affected Environment

Controlled and Uncontrolled Airspace

The Seattle ARTCC regulates air traffic in the region. Class E airspace is in effect above Naval Station Everett. Seattle International Airport Class B airspace is located above the southern edge of the ROI. The following Temporary Flight Restriction is in effect above Naval Station Everett due to national security:

"2/0451 - WA. FLIGHT RESTRICTIONS EVERETT, WA. EFFECTIVE IMMEDIATELY UNTIL FURTHER NOTICE. PURSUANT TO 14 CFR SECTION 91.137A(1) TEMPORARY FLIGHT RESTRICTIONS ARE IN EFFECT DUE TO NATIONAL SECURITY. ONLY RELIEF AIRCRAFT OPERATIONS UNDER THE DIRECTION OF DEPARTMENT OF DEFENSE ARE AUTHORIZED IN THE AIRSPACE AT AND BELOW 2000 FEET MSL WITHIN A 3 NAUTICAL MILES RADIUS OF (47 59 N/122 13 W) THE PAINE (PAE) VOR/DME 014 DEGREE RADIAL AT 4.53 NAUTICAL MILES. EXCLUDING THAT AIRSPACE WEST OF THE PAINE FLD RUNWAY 16R ILS LOCALIZER. UNLESS AUTHORIZED BY ATC FOR PURPOSES OF CONDUCTING ARRIVAL/DEPARTURE OPERATIONS. REGIONAL WATCH OFFICER 360-315-5123/FAX 360-315-5305 IS IN CHARGE OF THE OPERATION. SEATTLE /SEA/ AFSS 206-764-6609 IS THE FAA COORDINATION FACILITY. WIE UNTIL UFN"

Special Use Airspace

The nearest special use airspace is located approximately 40 kilometers (25 miles) west of Naval Station Everett and includes the Chinook and B Military Operating Areas, and the Admiralty Inlet Military Operating Area (figure 3.8.2-1).

En Route Airways and Jet Routes

Two Low Altitude air routes enter the ROI and terminate at Paine Field Airport. These include V-23 and V-287.

Airports/Airfields

Seattle-Tacoma International Airport is located approximately 56 kilometers (37 miles) south of Naval Station Everett. Snohomish County (Paine Field) Airport is about 5 miles southwest of Naval Station Everett. Several other airfields are located within the ROI including Harvey, Heineck, Large, Frontier, Arlington, and Whidbey.

3.8.3 BIOLOGICAL RESOURCES—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, NAVAL STATION EVERETT

Appendix B contains a general description of biological resources and the main regulations and laws that govern their protection.

3.8.3.1 Region of Influence

The ROI includes areas that may potentially be affected by the use of Naval Station Everett as a PSB for the SBX.

Airspace Over the Potential SBX Site at Naval Station Everett

Everett, Washington

Figure 3.8.2-1

GMD ETR Final EIS
Affected Environment

Naval Station Everett is located approximately 40 kilometers (25 miles) north of Seattle, Washington. The primary ship berthing facilities are Pier Alpha, a previously disturbed area that has mooring available on both sides, and Pier Bravo.

Examples of seabirds that occur in northern Puget Sound are glaucous-winged gulls, cormorants, pigeon guillemots, and tufted puffins. A variety of shorebirds and the bald eagle have also been observed in the vicinity. Seventy-two percent of seabirds in Puget Sound nest on Protection Island located at the mouth of Discovery Bay in the Strait of Juan de Fuca. (U.S. Fish and Wildlife Service, Pacific Region, 2002c)

The Puget Sound distinct population segment of bull trout (Salvelinus confluentus) was listed as federally threatened in November 1999. Bull trout are threatened by habitat degradation and fragmentation. The federally threatened Chinook salmon (Oncorhynchus tshawytscha) is also found in the Puget Sound. Threats to the chinook salmon include over-fishing, increased sedimentation, and decrease in water quality. Several threatened and endangered marine species occur in areas off the coast of Washington State. These include humpback, blue, fin, sei, and sperm whales; green, leatherback, and loggerhead sea turtles; and steller sea lions. The humpback whale, steller sea lion, and leatherback sea turtle may also occur in Puget Sound. (Washington State Department of Transportation, 2002)

3.8.4 HAZARDOUS MATERIALS AND HAZARDOUS WASTE—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, NAVAL STATION EVERETT

3.8.4.1 Region of Influence

The ROI for hazardous materials and hazardous waste includes those areas that may potentially be affected by the proposed deployment and use of the SBX to Naval Station Everett. The ROI includes fueling areas, support and maintenance operations and waste storage and disposal. Appendix B includes a detailed discussion of maritime and other laws, regulations, and standards concerning hazardous materials and hazardous waste.

3.8.4.2 Affected Environment

The 47.3-hectare (117-acre) site serves as homeport for a battle carrier group, including a Nimitz-class aircraft carrier, two guided missile destroyers, two destroyers and two guided missile frigates. The waterfront base is very compact and functionally oriented. Most available land is dedicated to ships’ support facilities, including storage areas, maintenance, and administration.

The Fleet and Industrial Supply Center Puget Sound Detachment Everett services the battle group and all organizations/detachments assigned to Naval Station Everett. The detachment is part of the Naval Supply System Command which supplies integrated support and supply chain management to naval operating units. Fleet and Industrial Supply integrated support services include waterfront/flight line husbandry, hazardous materials, repairables management, material handling, equipment management, local purchasing, training for supply business systems tools, supply assistance teams, consultative services and supply chain integration with commodity
pipelines. Supply chain management includes the systematic infrastructure for the specification, requirements definition, acquisition, material transport, inventory management, and logistic placement of materials for each of six main commodity areas. These commodity areas are aviation/ship repair parts and spares, petrol petroleum products, ordnance, subsistence, ship's store merchandise, and postal. All U.S. Navy materials at Naval Station Everett pass through the Fleet and Industrial Supply Detachment.

Hazardous materials are stored at the Hazardous Materials Center located in the Industrial and Logistics Support Zone of the Naval Station Everett Waterfront site. Limited, periodic ordnance handling and storage occurs at three berths at the Waterfront site. ESQD ordnance arcs are established around the berths when in use.

Operations of the carrier group generate considerable quantities of hazardous wastes. Naval Supply System Command protocol and procedures ensures safe handling and disposal of hazardous materials and wastes, and compliance with all pertinent state and federal regulations.

Biohazards and other hazardous wastes generated by the installation or the ships are handled and temporarily stored in the Industrial and Logistics Support Zone of the Naval Station Everett Waterfront site. Wastes are stored for up to 90 days in specific and specially designed areas before being trucked by an appropriately licensed contractor to designated disposal facilities. (U.S. Department of the Navy, Puget Sound Naval Shipyard, 1995)

Operations of the carrier group generate considerable quantities of hazardous wastes. To ensure safe handling and disposal of hazardous materials and wastes, the Navy complies with all pertinent state and federal regulations.

3.8.5 HEALTH AND SAFETY—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, NAVAL STATION EVERETT

3.8.5.1 Region of Influence
The ROI for health and safety includes those areas that may potentially be affected by the proposed deployment and use of the SBX to Naval Station Everett. The ROI for health and safety is based on the area where effects to human exposure, navigation and communication facilities/equipment (military and nonmilitary), fuels, and any existing EMR at Naval Station Everett may occur by the use of an XBR. Table 2.1.4-2 lists the maximum potential interference distances that define the ROI based on various subjects that could interact with the radar. Appendix B includes a general description of the health and safety resource area, and a detailed discussion of the laws, regulations, and standards concerning maritime safety and EMR.

3.8.5.2 Affected Environment
The Waterfront installation is located on the western limits of the City of Everett within a heavy industrial and manufacturing area. The Kimberly Clark Paper Company mill, timber loading and storage facilities, the U.S. Navy Reserve Center, the Port of Everett, and a Burlington Northern Santa Fe mainline are located east/southeast of the installation. The public Port of Everett Marina is located to the north.
Section 3.8.2 provides an overview of the airspace and airports in the Port Naval Station Everett ROI.

Base security requires that a 6.1- to 9.1-meter (20- to 30-foot) enclosure of open, undeveloped land surround the site perimeter.

Operations, maintenance and support activities at Naval Station Everett are performed in accordance with base SOPs and the Navy’s Safety and Occupational Health Program. Naval Station Everett received the Chief of Naval Operations Safety and Occupational Award in 1999 for the overall quality of base safety and occupation programs, mishap prevention and recording and contributions to the Safety and Occupational Health.

3.8.6 SOCIOECONOMICS—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, NAVAL STATION EVERETT

General socioeconomic impacts resulting from the proposed action can lead to an economic gain or loss for the community or area. Potential socioeconomic impacts of the project stem from the construction or operational activities, the duration and extent of displacement or modification of existing activities, and the diversion or temporary suspension of access associated with the Proposed Action. Impact analysis will focus on the following broad areas of economic or social impacts: displacement of populations, residences or businesses, housing/accommodation availability, employment/income, growth inducement and potential impacts to locally significant industries such as aerospace, shipping tourism, and retail.

3.8.6.1 Region of Influence

The ROI includes areas that may potentially be affected by the use of Naval Station Everett for the SBX. With regard to socioeconomics, this area would primarily include the City of Everett.

3.8.6.2 Affected Environment

Naval Station Everett is situated on 47 hectares (117 acres) adjacent to Port Gardner Bay within the City of Everett in Snohomish County, western Washington State. Everett, the county seat, is the largest city within the county (Puget Sound Regional Council, 2002) both in terms of population and area, covering 10,117 hectares (25,000 acres) of land and 3,884 hectares (9,600 acres) of water. Everett is situated approximately 45 kilometers (28 miles) north of Seattle, between the Cascade Mountains to the east and Puget Sound to the west, and adjacent to the mouth of the Snohomish River.

Historically an industrial city, Everett developed as a lumber and a mill town more than a century ago, and major industries have included mainly lumber, shingle mills, wood products manufacturers, ironworks, shipbuilders, fisheries, and canneries (Puget Sound Regional Council, 2002). The Port of Everett, immediately adjacent to Naval Station Everett, was created in 1918 and remains an important regional and international deep-water port. The Port of Everett Marina, with moorage for over 2000 vessels, is the second largest on the West Coast (Everett Business Journal, 2003). While the majority of the waterfront areas were claimed for industrial uses, other land uses adjacent to Naval Station Everett include commercial areas, a park, and residential areas, some of which overlook the base.
Population and Housing

The U.S. Bureau of the Census reported that the City of Everett, as of 2000, showed a population of 91,488 persons (Puget Sound Regional Council, 2002) and consisted of 15.0 percent of the county’s total population (606,024 persons). Everett has shown significant population growth over the last 2 decades, having risen 30.8 percent from 1990-2000 (69,961 persons) and 28.6 percent from 1980-1990. However, this rate of growth was consistently lower than that shown by Snohomish County, at 30.2 percent between 1990 and 2000 and 37.9 percent between 1980 and 1990. Between 1990 and 2000, the population of Washington state increased by 21.1 percent, with the county comprising 10.3 percent of the state’s population as of 2000.

As is shown in table 3.8.6.1, while remaining predominantly White, Everett is more racially and ethnically diverse than Snohomish County. Though proportionally small, Hispanic and Black/African American populations and persons of “some other race” within Everett are significantly elevated compared to the county. To a lesser extent, this is also the case for Asian, American Indian, and “two or more races” categories.

Source: U.S. Census Bureau, 2003a.

Income and Employment

The City of Everett shows significantly lower incomes than that of the county. The U.S. Bureau of the Census reported in 2000 that the City of Everett showed a per capita income of $20,557, 12.2 percent lower than the county average of $23,417. Similarly, as of 2000, the median household income of Everett was $40,100, a total of 24.4 percent lower than that of the county, at $53,060 (Puget Sound Regional Center, 2003). Everett also showed a significantly higher poverty rate than that of the county, at 12.9 percent poverty compared with 6.9 percent, respectively, as of 2000. The unemployment rate within Everett, at 5.3 percent as of 2000, was again significantly higher compared with 3.5 percent for the county (Puget Sound Regional Center, 2003).

The economy of Everett has changed significantly over the last 50 years, with a distinct fall in the extent of the lumber industry, the rise of papermaking and related products, and, most significantly, during the 1960s, the entrance of the aerospace industry to the region. Boeing maintains a dominant presence in the economy of Everett and the region today (Snohomish County Economic Development Council, 2002) and is the area’s largest employer (23,700).
There are also numerous other aerospace related companies (Everett Area Chamber of Commerce, 2003).

The Port of Everett, an internationally important deep-water facility containing 8 berths and covering approximately 40.4 hectares (100 acres) of land, handles approximately 907,184.7 metric tons (1 million tons) of cargo annually and is favored due to its proximity to the Far East and Alaska. Primary exports include lumber and agricultural goods. Major imports at the port include alumina ore and specialized aircraft parts. The Port also includes a large marina (Port of Everett, 2003).

Other major employers within Everett include John Fluke (electronic instruments), Verizon (telecommunications), and Kimberly-Clark (paper products), as well as employers in the healthcare, education, and government sectors (Snohomish County Economic Development Council, 2002). Naval Station Everett, with a full allotment of ships, including the naval aircraft carrier the USS Abraham Lincoln, employs approximately 6,087 personnel (Snohomish County Economic Development Council, 2002).

3.8.7 TRANSPORTATION—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, NAVAL STATION EVERETT

3.8.7.1 Region of Influence

The ROI includes areas that may potentially be affected by the use of Naval Station Everett for the SBX, as identified in section 2.3.1.8. No requirements for aviation or railway transportation are anticipated and thus, no impacts to those modes of transport are expected; consequently this section will predominately concern itself with ocean traffic, though roadway transportation is also addressed.

3.8.7.2 Affected Environment

Ocean Traffic

The Naval Station Everett is located next to the marina area of the city of Everett, Washington, about 40 kilometers (25 miles) north of Seattle on the northeast side of Possession Sound. Designed as a homeport for a U.S. Navy Battle Group, it accommodates the USS Abraham Lincoln (Aircraft Carrier, Nuclear-72), a Nimitz-class aircraft carrier, as well as several smaller surface combatants (GlobalSecurity.org, 2002a).

Access to and from Puget Sound berthing sites—including those for Naval Station Everett—is by the charted major ship travel channel, and all marine vessel traffic therein is regulated by the U.S. Coast Guard. Strict control of all shipping is maintained through a common radio channel. Ship traffic to Naval Station Everett requires sailing around the southern end of Whidbey Island and up the island’s eastern side to the Naval Station Everett berthing piers. Other than the CVN and Destroyer Squadron 9 that are homeported at Naval Station Everett, the only other large ship calling there is an occasional log carrier, which calls at the piers directly east of the carrier berth, providing visual contact at all times. (Department of the Navy, 1999)

Transition from the navigation channel to the CVN berthing pier, approximately 1,372 meters (1,500 yards), is executed under pilot advice and with the assistance of tugs (Department of the
Naval Station Everett, itself, has no tugboat complement. Tugs used at the port are primarily commercial because U.S. Navy tugs must travel from Naval Submarine Base Bangor in Washington, a distance of approximately 63 kilometers (34 nautical miles). It is required that requests for tugs be directed to Senior Officer Present Afloat (Admin) Puget Sound at least 72 hours in advance of anticipated time of movement. (GlobalSecurity.org, 2002a)

The primary ship berthing facility at Naval Station Everett is one long pier, designated as Pier Alpha, with mooring available on both its sides. Pier Alpha is 494 meters (1,620 feet) in length, with a 36.5-meter (120-foot) width. Pier Alpha's alongside depths range from 8.8 meters (29 feet) at the northeast end to 19.8 meters (65 feet) at the southwest end on the east side of the pier. (GlobalSecurity.org, 2002a) Since the pier is located close to the channel and deep water is available at the pier end, there is no other shipping traffic of concern during this movement. Recreational boating in the area is unaffected by CVN movements. When the CVN departs the tugs and pilot move the ship into the channel and assist until steerage is available. With the proximity of the piers to the channel and water depth, these vessel movements are easily managed. (Department of the Navy, 1999)

A second pier is Pier Bravo. Pier Bravo's western side is of rip-rap construction and acts as a breakwater. Its eastern, moorage side is slightly shorter than Pier Alpha, with similar width. (GlobalSecurity.org, 2002a)

An exclusion zone around Naval Station Everett was created by rule making with the U.S. Army Corps of Engineers and was published in the Code of Federal Regulations. The exclusion zone varies from a no standoff along the western side of Pier Bravo to a 91 meter (300 foot) standoff along the southern end of Pier Alpha and Pier Bravo, to a 182 meter (600 foot) standoff along the eastern side of Pier Alpha. Naval Station Everett coordinates ship movement and other activities with the Coast Guard, the Port of Everett, and the Tulalip Tribes.

Maritime traffic on Puget Sound is heavy; many large commercial vessels using the Ports of Everett, Seattle, Tacoma and others, enter and depart Puget Sound each day. Additional traffic on the Sound is created by the frequent runs of large Washington State vehicle and passenger ferries as they cross the Sound on generally east-west traffic routes that are perpendicular to normal inbound and outbound maritime traffic channels. Additionally, many recreational and commercial small craft operate throughout Puget Sound and adjacent waters. (GlobalSecurity.org, 2002b)

**Road Traffic**

Roadway transportation includes the local street and regional highway network in and around the City of Everett, which provides access to Naval Station Everett. Regional access is provided by Interstate 5, U.S. Route 2, and SR-529. Local access is provided by a street network within the City of Everett, which is generally arranged in a grid pattern. Key east-west streets accessing the station are Everett, Hewitt, and Pacific avenues, and key north-south streets are West Marine View Drive, Rucker Avenue, Broadway Avenue, and East Marine View Drive, all located between the station and Interstate 5; SR-529 runs along Broadway and Marine View Drive. (Department of the Navy, 1999)
Access onto West Marine View Drive is provided via the station’s two access gates, the Main Gate and the Service Gate. The station generates some 8,520 inbound and outbound vehicle trips per day, and an estimated 400 truck trips (Department of the Navy, 1999).

3.8.8 UTILITIES—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, NAVAL STATION EVERETT

3.8.8.1 Region of Influence
The ROI includes areas of Naval Station Everett that may potentially be affected by the SBX activities, as well as the area of potential construction of a new, environmentally controlled warehouse. This site has not been determined.

3.8.8.2 Affected Environment
All amenities are found on the piers, except for fuel. All fuel is barged in from the nearby Manchester Navy Fuel Depot, part of the Naval Supply Center (Department of the Navy, 1999) and located on the shores of Puget Sound.

Energy
Electrical service to the Naval Station Everett waterfront site is provided by the Snohomish County Public Utility District No. 1, which operates a 115-kV transmission system in the vicinity of the waterfront with dual power redundancy from both north and south. A nearby substation was upgraded to serve the adjacent Kimberly Clark Paper Company plant. A 115-kV dedicated substation has been constructed at the waterfront site and will accommodate a potential 7-ship mix and onshore installation electrical loads. The total available capacity at the site is 80,000 kVA, with a steady load of 36,000 kVA.

Water
The City of Everett, Public Works Department, Water Division serves the Naval Station Everett waterfront site, producing some 116,000 million liters (30,700 million gallons) of water annually for citywide distribution, as well as distribution to nearby cities and water districts. The main water distribution line to the waterfront site runs along Norton Avenue. The distribution system has tested at an estimated peak flow rate of 17 million liters (4.55 million gallons) per day.

Within the installation, the potable water system consists of a looped underground distribution system and supply main serving the berthing piers. To provide ships with potable water, supply mains are located in the “utilidor” (the local utility corridor) and in the pier and wharf utility chase. These lines accommodate a wide variety of ship mixes with a 13,250-liter (3,500-gallon) per minute flow. Total available capacity is 10.2 million liters (2.7 million gallons) per day, with a typical load of 3.4 million liters (900,000 gallons) per day.

Wastewater
The City of Everett Sewer Department provides services to the city and surrounding districts. Two existing sewer and pumping systems, gravity trunk lines ranging from 30.5 to 91.4 centimeters (12 to 36 inches) in diameter, serve the waterfront site and surrounding businesses.
The installation’s sanitary sewer system consists of an underground collection system, pump stations, and an attenuation tank. A main pump and pressure main delivers flows to the City of Everett sewer system. Collection pump stations are required due to the proximity to sea level elevation. The sanitary sewer system is monitored in the Steam and Air Plant, and maintains an available capacity of 11.4 million liters (3 million gallons) per day with a steady load of 3.8 million liters (990,000 gallons) per day.

Solid Waste
Refuse collection in Everett is via private contractor. Solid waste transfer facilities and services are provided by the Snohomish County Department of Public Works, Solid Waste Division. Most area refuse is trucked to the Everett Transfer Station operated by the county, which, along with the Cathcart Landfill, has limited capacity.

Solid waste generated on the waterfront site and by transient Navy ships ranges from less than 1.01 metric tons (1 ton) per day to 7.6 metric tons (7.5 tons) per day, depending on the number of ships at homeport. The average demand is 4.6 metric tons (4.5 tons) per day.

3.8.9 VISUAL AND AESTHETIC RESOURCES—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, NAVAL STATION EVERETT

Appendix B includes a description of visual and aesthetic resources and a methodology for assessing visual and scenic values.

3.8.9.1 Region of Influence
The ROI includes areas that may potentially be affected by the use of Naval Station Everett for the SBX as identified in section 2.3.1.8.

3.8.9.2 Affected Environment
Primarily the affected environment consists of Naval Station Everett (homeport of the USS Abraham Lincoln) and the surrounding properties which include a paper mill, other industrialized facilities, a park, commercial sites, and residential properties. Immediately adjacent on the south and east to the naval station are the Port of Everett’s log export facility and the Kimberly Clark Paper Company mill. Parking areas, recreational facilities, and support buildings occupy the northern part of the base while the southern end is occupied by industrial facilities, piers, and ships. (U.S. Department of the Navy, Puget Sound Naval Shipyards, 1995)

Those that may be affected by the Proposed Action from a visual aspect include employees of the naval station and the other industrial sites, visitors to the naval station and surrounding areas, and in particular visitors to the park and the homeowners overlooking the site.
3.9 PORT ADAK—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE

The proposed GMD ETR activities could have an effect on air quality, airspace, biological resources, hazardous materials and waste, health and safety, utilities, and visual and aesthetic resources at Port Adak. These resource areas are summarized in the following sections.

By nature of its marine mission and use of existing homeport facilities, SBX support and operational activities will not result in any adverse effects to cultural resources, geology and soils, land use, noise, socioeconomics, transportation, and water resources. Consequently, this section will not include further analysis of these resources other than the summary in the following paragraphs.

Cultural
There are not expected to be any ground disturbing activities within areas where cultural resources are located. While some mooring locations may have traditional importance, such as native fishing grounds, the SBX would occupy a very small area on a temporary basis.

Geology
While potential warehouse and administration facility construction activities could result in limited clearing and excavation for building foundations, it is not expected to create any adverse erosion effects to geology or soils. Construction activities would follow standard guidelines.

Land Use
Land use impact would be minimal since the proposed activities would occur on the water at the pier or near an existing mooring location and would not produce a change in the type of land utilization in the immediate or surrounding areas. Land utilization in surrounding areas would not change.

Noise
No sensitive receptors would be disturbed by the proposed intermittent and short-term activity, and noise levels would to be below OSHA workplace standards.

Socioeconomics
As a result of its isolation, limited population, and local economic activity, only minor positive socioeconomic impacts would occur.

Transportation
The few additional personnel would not affect transportation. Shipping of project-related materials, as well as transportation of personnel, would utilize air, roadway, and shipping/ferrying routes that are equipped to handle both the loads and frequency of project demands. Any increase in daily trips by support personnel would utilize existing transportation infrastructure. Shared vehicle and/or off-peak hour travel would further serve to minimize effects on transportation levels.
Water Resources
Impacts to water resources would be negligible, similar to other large marine vessels.

3.9.1 AIR QUALITY—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PORT ADAK

3.9.1.1 Region of Influence
The ROI includes areas that may potentially be affected by the use of Port Adak for the SBX, including the mooring sites identified in section 2.3.1.9.

3.9.1.2 Affected Environment
Climate
Adak Island’s climate is characterized as polar maritime one with persistent overcast skies, high winds, frequent and often violent storms, and a narrow range of temperature fluctuation throughout the year. Weather on the island tends to be localized; fog, low ceilings, precipitation, and clear weather are all possible within a distance of a few miles. (Naval Facilities Engineering Command, Engineering Field Activity, Northwest, 2001)

Local shifts and rapid changes in velocity characterize the wind conditions on Adak. Average wind speed is 18.5 kilometers (11.5 miles) per hour, with gusts reaching 185 kilometers (115 miles) per hour during winter storms. Summer months also experience high winds, with gusts reaching up to 92.6 kilometers (57.5 miles) per hour. Winds tend to be from the southwest.

Monthly temperature varies from a low of 0.5°C (33°F) in February to a high of 11°C (51°F) in August.

Annual precipitation is about 137 centimeters (54 inches), usually in the form of rain. Average monthly precipitation varies from a high of 17.8 to 20.3 centimeters (7 to 8 inches) in November and December to a low of 3 inches in June and July. Approximately 254 centimeters (100 inches) of snow falls each year. However, due to the relatively warm temperature in Adak, snow rarely exceeds 0.31 to 0.62 meter (1 to 2 feet) in depth. (Adak Update.com, 2002)

Regional Air Quality
The entire area in and around the Aleutian chains is designated as an attainment area for ambient concentrations of air pollutants. Although there is little actual ambient air quality monitoring in the Aleutians, the climate of the islands is conducive to good air quality, except in times of very high winds and dry weather when blowing natural dust can occur. The generally wet conditions help to reduce windblown dust. (Naval Facilities Engineering Command, Engineering Field Activity, Northwest, 2001)

Existing Emission Sources
The Alaska Department of Environmental Conservation Division of Air and Water Quality does not maintain air monitoring activities in the area. Existing emissions surrounding Port Adak stem primarily from regional volcanic activity.
3.9.2 AIRSPACE—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PORT ADAK

Appendix B includes a general description of airspace.

3.9.2.1 Region of Influence

The ROI for airspace at Port Adak includes the airspace over and surrounding the potential SBX interference areas that extend from the mooring location at Finger Bay, east of Port Adak (figure 3.9.2-1).

3.9.2.2 Affected Environment

Controlled and Uncontrolled Airspace

The airspace in the ROI is composed of Class A airspace from 5,486 meters (18,000 feet) mean sea level up to and including FL 600 (18,288 meters or 60,000 feet). Below 5,486 meters (18,000 feet), the airspace is composed largely of Class G (uncontrolled) airspace, except for the area around Adak, which is Class E airspace. The Class E airspace extends upward from 213 meters (700 feet) above the surface within a 11-kilometer (5.9-nautical-mile) radius of Adak, and also includes that airspace extending upward from 366 meters (1,200 feet) above the surface within a 18-kilometer (9.7-nautical-mile) radius of Port Adak (see figure 3.9.2-1). The service times for the Class E airspace is Monday through Friday 1800 to 0300 Greenwich Mean Time. At other times the airspace is Class G. There is no Class B, Class C, or Class D airspace in the ROI. (National Aeronautical Charting Office, 2002)

The airspace ROI lies within the Anchorage Oceanic Control Area/Flight Information Region (CTA/FIR) and within the U.S. Alaskan Air Defense Identification Zone. Aircraft separation and safety advisories are provided by air traffic control, the Anchorage ARTCC.

Special Use Airspace

There is no special use airspace in the ROI.

En Route Airways and Jet Routes

There is one en route low altitude airway (G8) connecting to Shemya Island to the west and Unalaska to the East. A second low altitude airway (G1) connects from Adak to Cold Bay. One high altitude jet route (V 480) runs from Adak to the northeast.

Adak is located on the southern edge of the great circle route from North America to the Far East. One of these routes (J 115) enters Adak from the east, and three routes (J 115, R 451, and R 336) enter Adak from the west.

Airports/Airfields

Adak Airport is the only airport in the ROI. It includes two runways, approximately 2,380 meters (7,800 feet) and 2,315 meters (7,600 feet) in length. The airport is attended continuously. (National Aeronautical Charting Office, 2002)
Airspace Over the Potential SBX Site at Port Adak

Adak, Alaska

Figure 3.9.2-1

Potential Interference Distances

- 22.4 km Full Commercial COMM
- 19 km Full Aircraft - Main Beam
- 15.4 km 65% Commercial COMM
- 12.1 km 65% Aircraft - Main Beam
- 7.5 km Full (Air) - EEDs Presence/Shipping
- 7.1 km Full Military COMM
- 4.8 km 65% (Air) - EEDs Presence/Shipping
- 3.5 km 65% Military COMM

Note:
- Full = Fully Populated SBX Radar
- 65% = 65% Populated SBX Radar

3.9.3 BIOLOGICAL RESOURCES—SEA-BASED TEST X-BAND RADAR
PRIMARY SUPPORT BASE, PORT ADAK

Appendix B contains a general description of biological resources and the main regulations and laws that govern their protection.

3.9.3.1 Region of Influence

The ROI includes areas that may potentially be affected by the use of Port Adak for the SBX, including the mooring sites as identified in section 2.3.1.9.

3.9.3.2 Affected Environment

Terrestrial biological resources are not addressed since those areas where elements of the Proposed Action would take place onshore are already developed and disturbed. The Aleutian shield fern (*Polystichum aleuticum*), which is only found on Adak Island, is located outside the ROI.

Adak is located approximately 2,092 kilometers (1,300 miles) southwest of Anchorage in the Aleutian Islands. Adak is part of the Aleutian Islands Unit of the Alaska Maritime Wildlife Refuge and is within one of the world's richest fishing regions. Currently the Adak Fisheries Development Council processes cod, crab, halibut, and other bottom fish (Alaska.net, 2002). Coho salmon, pink salmon, and Dolly Varden are known to spawn in most streams that drain into Kuluk Bay, north of the proposed SBX mooring location (Alaskan Command, 1996).

Various seabirds and water fowl overwinter around Adak Island. A few seabird nesting colonies are located in Clam Lagoon, north of the proposed SBX mooring location. Several bird species that nest on Adak Island are the mallard, pelagic and red-faced cormorant, mallard, common eider, bald eagle, Arctic and Aleutian tern, marbled murrelet, and tufted puffin (U.S. Fish and Wildlife Service, 1987).

Steller sea lions, sea otters, harbor seals, and whales occur around Adak Island. The recently delisted Aleutian Canada goose can occur in the area during migration. A Steller sea lion rookery is located on the southwestern portion of the island and a haulout area is located at Cape Moffett, northwest of the proposed SBX mooring location (Alaskan Command, 1996). Sea otter numbers have declined in Kuluk Bay recently, due perhaps to increased predation by killer whales. The population dropped by 76 percent from 1993 to 1997. (U.S. Geological Survey, 1998)

3.9.4 HAZARDOUS MATERIALS AND HAZARDOUS WASTE—SEA-BASED TEST
X-BAND RADAR PRIMARY SUPPORT BASE, PORT ADAK

3.9.4.1 Region of Influence

The ROI includes areas that may potentially be affected by the use of Port Adak for the SBX, including the mooring sites identified in section 2.3.1.9.
3.9.4.2 Affected Environment

Adak Island is approximately 45 kilometers (28 miles) long with a total land area of 725 square kilometers (280 square miles). Adak’s water area totals approximately 13 square kilometers (4.9 square miles). The island’s geographic location makes it a key supply and logistical support center for recreational/private, commercial, and government air and marine transport routes for the western Aleutian Islands, Bering Sea, and Pacific Ocean.

Hazardous Materials Management

The most prevalent hazardous material on Adak is fuel. Adak Fuels operates a fueling terminal on what was a naval base. The underground diesel, gasoline and jet fuel storage system at the Sweeper Cove Terminal has an approximate 83-million-liter (22-million-gallon) holding capacity. Adak Fuels also supplies petroleum lubricants and greases to the marine vessels.

Other hazardous materials support Terminal and Port operations. These materials may include, gasoline for equipment and vehicles, propane, organic solvents, heat transfer fluids, glycol-based coolants, refrigerants, protective coatings, fire suppression chemicals, and cleaning agents.

Hazardous Waste Management

Hazardous waste is generated from various routine and preventative maintenance and repair activities at the Port and Sweeper Cover Terminal. These wastes may include spent thinners, cleaning solvents, flammable paints and coatings, corrosive acids, flammable adhesives, used oils containing chlorinated compounds and spent coolants. Sludge and residues removed from equipment and sumps may also be characterized as hazardous.

3.9.5 HEALTH AND SAFETY—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PORT ADAK

3.9.5.1 Region of Influence

The ROI includes areas that may potentially be affected by the use of Port Adak for the SBX, including the mooring sites identified in section 2.3.1.9. The ROI for health and safety is based on the area where effects to human exposure, navigation and communication facilities/equipment, fuels and any existing EMR at Port Adak may occur by the use of an XBR. Table 2.1.4-2 lists the maximum potential interference distances that define the ROI based on various subjects that could interact with the radar. Appendix B includes a general description of the health and safety resource area and a detailed discussion of the laws, regulations, and standards concerning maritime safety and EMR.

3.9.5.2 Affected Environment

The Coast Guard 17th District provides marine inspections, casualty investigations, fishing vessel inspections, harbor patrol, pollution response and facility contingency planning for Port Adak.

The Sweeper Cove Terminal maintains an Oil Spill Prevention and Response Plan in compliance with State of Alaska and federal requirements.
3.9.6 UTILITIES—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PORT ADAK

3.9.6.1 Region of Influence
The ROI includes areas that may potentially be affected by the use of Port Adak for the SBX, including the mooring site, Finger Bay, identified in section 2.3.1.9.

3.9.6.2 Affected Environment

Energy
Adak Electric Utility, under the auspices of the City of Adak, provides area electricity. The electric system has excess capacity to meet future commercial and industrial development. Adak Electric Utility has the capability of handling 14.5 MW with an average daily demand of only 1 MW per day (Hines, 2002).

Water
Currently and historically, all Adak water supplies (including potable water) have been obtained from surface water. Previously, potable water was available to accommodate as many as 5,000 people via two water systems from three different sources (Naval Facilities Engineering Command, Engineering Field Activity, Northwest, 2002). In March 1997, Naval Complex Adak was closed and ceased to operate as a military facility, reducing the population from 2,500 to less than 500 people. This reduction in population permitted the closure of certain of the public water systems; one of these, Nurses' Creek, is in the process of shutting down (Hines, 2002). Still in use is the Lake Bonnie Rose system, which is operated as a Class A public water system (Adak Update.com, 2002). City water is connected to all buildings and homes. The current system is capable of producing over 3.8 million liters (1.0 million gallons) per day, with an average demand of about 1.14 million liters (300,000 gallons) per day (Hines, 2002).

Wastewater
Adak Wastewater Utility maintains a wastewater treatment system which discharges its treated water through a marine outfall line to Kuluk Bay (I Love Alaska.com, 2002). Up to approximately 3.02 million liters (800,000 gallons) per day runs through this system, of which less than 1 percent is actually wastewater. Wastewater levels are not monitored directly. (Hines, 2002)

Solid Waste
The Class 3 landfill, the Husky Road Landfill, has been in use since approximately 2000, and is not expected to reach capacity until 2010 (Hines, 2002). It is estimated that 20 percent of its capacity has been used thus far. All paper products are burned (Hines, 2002), and refuse is burned or baled before disposal in the landfill.
3.9.7 VISUAL AND AESTHETIC RESOURCES—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PORT ADAK

Appendix B includes a description of visual and aesthetic resources and the analysis of the potential impacts from the Proposed Action.

3.9.7.1 Region of Influence

The ROI includes areas that may potentially be affected by the use of Port Adak for the SBX, including the mooring site identified in section 2.3.1.9.

3.9.7.2 Affected Environment

The affected environment for Adak, Alaska consists of Port Adak and the surrounding areas; particularly those areas surrounding the potential mooring site at Finger Bay. Until recently, Port Adak has primarily been used as a naval base, and as such, there are many remaining facilities associated with naval activities within the affected environment.

Typically, the Adak climate is wet, foggy, stormy, windy, and overcast. Heavy rains and blowing snow showers inhibit much of the visibility, which usually remains below 1.6 kilometers (1 mile) horizontally.

Vegetation on the island is primarily tundra floral consisting of dwarf willows, alders, grasses, moss, and lichens. Coastal areas support beach wild rye, while offshore the sea water supports kelp and algae.

The port facilities at Adak are located on one of the largest areas of flat land on the island. There is a rolling hill (elevation: 150 meters [492 feet]) situated on the peninsula between Port Adak and the potential mooring site. (State of Alaska, Department of Community and Regional Affairs, 1996)

Although cruise ships do occupy the port occasionally, the only people that ordinarily inhabit Adak are all associated with the port facilities or other small businesses and would not be especially sensitive to scenic quality.
3.10 PORT OF VALDEZ—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE

The proposed GMD ETR activities could have an effect on air quality, airspace, biological resources, hazardous materials and waste, health and safety, transportation, utilities, and visual and aesthetic resources at Port of Valdez. These resource areas are summarized in the following sections.

By nature of its marine mission and use of existing homeport facilities, SBX support and operational activities will not result in any adverse effects to cultural resources, geology and soils, land use, noise, socioeconomics, and water resources. Consequently, this section will not include further analysis of these resources other than the summary in the following paragraphs.

Cultural

There are not expected to be any ground disturbing activities within areas where cultural resources are located. While some mooring locations may have traditional importance, such as native fishing grounds, the SBX would occupy a very small area on a temporary basis.

Geology

While potential warehouse and administration facility construction activities could result in limited clearing and excavation for building foundations, it is not expected to create any adverse erosion effects to geology or soils. Construction activities would follow standard guidelines.

Land Use

Land use impact would be minimal since the proposed activities would occur on the water at the pier or near an existing mooring location and would not produce a change in the type of land utilization in the immediate or surrounding areas. Land utilization in surrounding areas would not change.

Noise

No sensitive receptors would be disturbed by the proposed intermittent and short-term activity, and noise levels would be below OSHA workplace standards.

Socioeconomics

As a result of its isolation, limited population and local economic activity, only minor positive socioeconomic impacts would occur.

Transportation

The few additional personnel would not affect the transportation. Shipping of project-related materials, as well as transportation of personnel, would utilize air, roadway, and shipping/ferrying routes that are equipped to handle both the loads and frequency of project demands. Any increase in daily trips by support personnel would utilize existing transportation infrastructure. Shared vehicle and/or off-peak hour travel would further serve to minimize effects on transportation levels.
Water Resources
Impacts to water resources would be negligible, similar to other large marine vessels.

3.10.1 AIR QUALITY—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PORT OF VALDEZ

3.10.1.1 Region of Influence
The ROI includes areas that may potentially be affected by the use of the Port of Valdez for the SBX, including the mooring sites identified in section 2.3.1.10.

3.10.1.2 Affected Environment
Climate
Climate in Valdez is part of a maritime zone that includes southeastern Alaska, the south coast, and southwestern islands. Annual wind speed averages 10 kilometers (6.2 miles) per hour, typically from the east-northeast. The annual mean temperature is 3°C (38°F), with monthly mean averages ranging from -6°C (21°F) in January to 13°C (55°F) in July.

Annual precipitation at Valdez reaches 162.6 centimeters (64 inches), with annual snowfall of approximately 802 centimeters (316 inches). The average number of days with heavy fogs, with visibility equal to or less than 0.40 kilometer (0.25 mile), for Valdez is 15.8. (U.S. Department of the Interior, Bureau of Land Management, 2002)

Regional Air Quality
The Port of Valdez is located within the South Central Intrastate Air Quality Control Region. The area is designated as being in attainment for all NAAQS.

Existing Emission Sources
The Valdez Marine Terminal is the dominant emission source in the Valdez area; it contributes 90 percent or more of each criteria pollutant and volatile organic compound to the total emissions. Table 3.10.1-1 lists the Valdez Marine Terminal’s annual emissions, as well as annual emissions for adjacent facilities.

| Table 3.10.1-1: Summary of Emissions of Regulated Air Pollutants in the Port of Valdez |
|---------------------------------|-----------------|-----------------|-----------------|-----------------|-----------------|
|                                | PM-10           | Sulfur Dioxide  | Carbon Monoxide | Nitrogen Dioxide | Volatile Organic |
|                                | metric tons     | metric tons     | metric tons     | metric tons     | Compounds       |
|                                | (tons)/year     | (tons)/year     | (tons)/year     | (tons)/year     | metric tons     |
| Valdez Marine Terminal         | 252.2 (278)     | 1,593.9 (1,757) | 124.3 (137)     | 1,431.5 (1,578) | 3,142.5 (3,464) |
| Adjacent Facilities*           | 27.2 (30)       | 116.1 (128)     | NA              | 100.7 (111)     | NA              |

a = includes the Petro Star Refinery, the City of Valdez, and the Valdez Airport
NA = Not available
3.10.2 AIRSPACE—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PORT OF VALDEZ

Appendix B includes a general description of airspace.

3.10.2.1 Region of Influence

The ROI for airspace at Port of Valdez includes the airspace over and surrounding the potential SBX interference areas that extend from the mooring location south of the City of Valdez, Alaska (figure 3.10.2-1).

3.10.2.2 Affected Environment

Controlled and Uncontrolled Airspace

The airspace in the ROI is composed of Class A airspace from 5,486 meters (18,000 feet) mean sea level up to and including FL 600 (18,288 meters or 60,000 feet). Below 5,486 meters (18,000 feet), the airspace is composed largely of Class G (uncontrolled) airspace, except for the area around Valdez Pioneer Airport, which is Class E airspace. The Class E airspace extends upward from 213 meters (700 feet) above the surface within a 11-kilometer (5.9-nautical-mile) radius of Valdez Pioneer Airport (see figure 3.10.2-1). There is no Class B, Class C, or Class D airspace in the ROI. (U.S. Department of Transportation, 2002i)

The airspace ROI lies within the Anchorage Oceanic CTA/FIR and within the U.S. Alaskan Air Defense Identification Zone. Aircraft separation and safety advisories are provided by air traffic control, the Anchorage ARTCC.

Temporary flight restrictions (as of May 2003) include the following:

"1109 - PART 1 OF 2 FLIGHT RESTRICTIONS VALDEZ CLASS E AREA EFFECTIVE IMMEDIATELY UNTIL FURTHER NOTICE, PURSUANT TO 14 CFR SECTION 91.137A(2), TEMPORARY FLIGHT RESTRICTIONS ARE IN EFFECT FOR THE VALDEZ CLASS E AREA. THE VALDEZ CLASS E AREA IS DEPICTED AS THE ENCLOSED AREA BOUNDED BY THE MAGENTA 700 FEET BORDER ON THE ANCHORAGE AERONAUTICAL SECTIONAL CHART AND IS DEFINED AS THE 6.6 NM RADIUS OF THE VALDEZ AIRPORT AND WITHIN 3.1 NM EACH SIDE OF THE VALDEZ LOCALIZER FRONT COURSE EXTENDING FROM THE 6.6 NM RADIUS TO 21.6 NM SOUTHWEST OF THE AIRPORT. ALTITUDES: SURFACE UP TO AND INCLUDING 8,000 FEET MSL. TIMES: 24 HOURS/7 DAYS A WEEK ALL AIRCRAFT ENTERING OR DEPARTING THE VALDEZ CLASS E AREA SHALL CONTACT JUNEAU AFSS VHF 122.2, 122.4 OR 122.55 WITH THEIR CALLSIGN, POSITION, ALTITUDE, AND ROUTE OF FLIGHT. END PART 1 OF 2 WIE UNTIL UFN"

"PART 2 OF 2 FLIGHT RESTRICTIONS VALDEZ CLASS E AREA IN RESPONSE TO THE TERRORIST ATROCITIES OF SEPTEMBER 11, 2001, THIS FLIGHT RESTRICTION IS REQUIRED TO ESTABLISH A COMMUNICATION REQUIREMENT TO MONITOR ALL AIRCRAFT AROUND THE VALDEZ OIL TERMINAL AND TO ESTABLISH A NO FLY AREA OVER THE OIL TERMINAL AND DOCKS. THE NO FLY AREA IS DEFINED AS ONE (1) NM RADIUS CIRCLE CENTERED ON THE 651 FEET MSL (300 FEET AGL) RADIO TOWER LOCATED AT THE VALDEZ OIL TERMINAL. THIS TOWER IS DEPICTED ON THE ANCHORAGE AERONAUTICAL SECTIONAL CHART AND IS LOCATED AT LAT. 61 05" 06 N LONG. 146 23"19" W. AIRCRAFT WITH NO RADIO CAPABILITY: PRECOORDINATE WITH JUNEAU AFSS ON TIMES, ALTITUDES, AND ROUTE OF FLIGHT. THE FAA COORDINATION FACILITY IS JUNEAU AFSS, PHONE 907-586-7382. END PART 2 OF 2 WIE UNTIL UFN "

GMD ETR Final EIS 3-163
Figure 3.10.2-1

Airspace Over the Potential SBX Site at Port of Valdez

Valdez, Alaska

Special Use Airspace
There is no special use airspace in the ROI.

En Route Airways and Jet Routes
There is one en route low altitude airway (A7) connecting to Anchorage to the west. One low altitude airway (V 481) crosses the ROI approximately 3 kilometers (1.6 nautical miles) east of the Valdez Pioneer airport. One high altitude jet route (J167) is located directly above V481.

Valdez is located on the southern edge of the great circle route from North America to the Far East. Two of these routes (NCA 13 and NCA 20) run east–west across the ROI above Valdez. The ground trace of these routes is about 6 kilometers (3.2 nautical miles) south and 6 kilometers (3.2 nautical miles) north of Valdez Pioneer Airport, respectively.

Airports/Airfields
Valdez Pioneer Airport is the only airport in the ROI. It includes one runway, approximately 2,380 meters (6,500 feet) in length. The airport is attended from 6:00 a.m. to 8:00 p.m. (U.S. Department of Transportation, 2002j)

3.10.3 BIOLOGICAL RESOURCES—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PORT OF VALDEZ

Appendix B contains a general description of biological resources and the main regulations and laws that govern their protection.

3.10.3.1 Region of Influence
The ROI includes areas that may potentially be affected by the use of the Port of Valdez for the SBX, including the mooring sites as identified in section 2.3.1.10.

3.10.3.2 Affected Environment
Terrestrial biological resources are not addressed since those areas where elements of the Proposed Action would take place onshore are already developed and disturbed.

The Port of Valdez is located in a deepwater fjord in northeast Prince William Sound. It lies 193 kilometers (120 air miles) east of Anchorage, or 490 kilometers (305 miles) by the Richardson and Glenn Highways. Large populations of marine and anadromous fish occur in Prince William Sound such as sockeye, pink, coho, Chinook, and chum salmon, Pacific herring, Pacific halibut, and sablefish. All estuarine and marine areas out to the Economic Exclusion Zone of the United States used by Alaskan Pacific salmon are designated as Essential Fish Habitat for salmon fisheries. Salmon occur in the Sound mainly from June through September as they return from the ocean to spawn (National Wildlife Federation, 2001). Essential Fish Habitat has also been designated for scallops and Gulf of Alaska ground fish in Port Valdez. (Bureau of Land Management, 2002)
Prince William Sound is an important overwintering area for sea ducks such as scoters, cormorants, harlequin duck, Barrow’s goldeneye, oldsquaw, and mergansers (Bureau of Land Management, 2002). Some of the more common seabirds occurring in the sound are the murrelet, black-legged kittiwake, glaucous-winged gull, fork-tailed petrel, and mew gull (National Wildlife Federation, 2001; Alaska.net, 2002). Small groups of threatened Steller’s eiders are occasionally found in Prince William Sound during the winter (Bureau of Land Management, 2002).

Prince William Sound provides habitat for humpback, killer, and minke whales, sea otters, Steller sea lions, harbor seals, and Dall and harbor porpoise. Killer and minke whales are observed year round. Humpback whales are the most abundant whale species in Prince William Sound and feed there in the summer. However, they are found primarily in the southwestern portion of the Sound, away from Port Valdez. Most of the humpback whales migrate to Hawaii and Mexico for calving in the winter (National Wildlife Federation, 2001). The population of sea otters affected by earthquakes and the Exxon Valdez oil spill appeared to be recovering by 1993. The overall population of sea otters in Prince William Sound increased during the 1990s. The Steller sea lions in Prince William Sound are part of the endangered western stock. None of the critical habitat designated for the Steller sea lion occurs in Port Valdez. Although harbor seals are abundant in Prince William Sound year round, their long-term decline there (since 1970s) has not ended. Dall and harbor porpoises are both abundant (more abundant in summer) and widespread in Prince William Sound. (Bureau of Land Management, 2002)

3.10.4 HAZARDOUS MATERIALS AND HAZARDOUS WASTE—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PORT OF VALDEZ

3.10.4.1 Region of Influence

The ROI includes areas that may potentially be affected by the use of the Port of Valdez for the SBX, including the mooring sites as identified in section 2.3.1.10.

3.10.4.2 Affected Environment

Prince William Sound includes approximately 28,490 square kilometers (11,000 square miles) of shoreline, islands, and open water. The Port of Valdez is located in a northern deepwater fjord of Prince William Sound. Within the Port, the Valdez Container Terminal consists of a 213-meter (700-foot) floating concrete dock tied to an 8.5-hectare (21-acre) marshalling yard by two 61-meter (200-foot) ramps. The terminal is designed as a multi-purpose berth to accommodate the commercial fishing industry, seafood processing plants, a grain terminal and tourist industry.

The port also serves as the southern terminal of the Trans-Alaska Pipeline System (TAPS). The TAPS terminal occupies approximately 404.7 hectares (1,000 acres) of land owned by the Alyeska Pipeline Service Company (APSC). The TAPS Terminal serves to store and load crude oil and houses the Operations Control Center (OCC) for the TAPS. The total holding capacity in the crude oil tanks at the Valdez Terminal is approximately 9.18 billion barrels. The average working inventory of the tanks is approximately 7.8 billion barrels, or approximately 85 percent of maximum capacity. The OCC monitors and controls the movement of oil through the pipeline via a series of satellite, cable, and terrestrial microwave radio systems.
Hazardous Materials Management

The most prevalent hazardous material at the TAPS Terminal is diesel fuel, with approximately 30 million liters (8 million gallons) nominally being stored at any given time. Other hazardous materials used at the Terminal support Terminal and TAPS operations. These materials include gasoline for equipment and vehicles, propane, organic solvents, heat transfer fluids, glycol-based coolants, refrigerants, protective coatings, fire suppression chemicals, and cleaning agents.

The APSC Hazardous Materials Business Model defines the appropriate administrative procedures for management of hazardous materials at the Terminal and other locations in the APSC system. Procedures for implementing the Hazardous Materials Business Model are provided in the TAPS Environmental Protection Manual, EN-43-1. Purchase and use of hazardous materials by APSC personnel and TAPS contractors are centrally controlled through the APSC systemwide Hazardous Materials Consolidation and Redistribution (HAZCORE) Program. In addition to procurement and inventory management, HAZCORE databases allow access to MSDS and ensure that employee hazardous material training is current and compliant with OSHA and State of Alaska requirements.

Hazardous materials are typically delivered to a central APSC warehouse in Anchorage, Alaska and shipped by truck (commercial carrier or APSC vehicle) to the terminal, maintenance or equipment yards, or pump station. Hazardous materials delivered to the terminal are stored in dedicated areas within designated buildings. Fuels are delivered in bulk by commercial carriers and transferred to above ground storage tanks at the terminal or other appropriate location. Limited quantities of hazardous materials and fuels may occasionally be stored in temporary facilities or portable tanks at a designated location for specific jobs.

APSC submits annual Emergency Planning and Community Right-to-Know Act Tier II reports to state and federal authorities. The terminal has an SPCC Plan and works with local emergency planning authorities in developing site specific contingency plans for hazardous material storage and usage locations.

Hazardous Waste Management

The Valdez Marine Terminal is considered a large quantity generator. Hazardous waste is generated from various routine and preventative maintenance and repair activities at the terminal. These wastes include spent thinners, cleaning solvents, flammable paints and coatings, corrosive acids, flammable adhesives, used oils containing chlorinated compounds, spent coolants, spent aerosol cans and crushed fluorescent lights. Sludge and residues removed from equipment and sumps may also be characterized as hazardous. The largest quantity of potentially hazardous waste is from tank bottoms and “materials in process” that are periodically removed from equipment and storage tanks. Some spill debris and containment media may also be characterized as hazardous.

The TAPS Environmental Protection Manual, EN-43-2 also establishes procedures for management of hazardous waste. Hazardous waste generated at the terminal is accumulated in a designated waste accumulation area within dedicated buildings. All hazardous waste accumulation areas have secondary containment features. A licensed contractor collects and transports the waste via truck to a terminal in Anchorage, Alaska where the waste is then shipped via barge or rail to permitted Treatment, Storage, Disposal, and Recycling Facilities outside of Alaska. All wastes are transported in accordance with appropriate DOT and state specifications.
Limited quantities of special wastes could potentially be generated from TAPS operations. Such wastes would include PCB wastes (contained in the dielectric fluids of electrical equipment), asbestos wastes, pesticide wastes, drag reducing agent wastes, spent glycols, tanker garbage, asphalt, spent sandblast media, naturally occurring radioactive material, spill debris and remediation waste. Handling procedures are waste specific and in accordance with applicable state and federal specifications.

3.10.5 HEALTH AND SAFETY—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PORT OF VALDEZ

3.10.5.1 Region of Influence

The ROI includes areas that may potentially be affected by the use of the Port of Valdez for the SBX, including the mooring sites as identified in section 2.3.1.10. The ROI for health and safety is based on the area where effects to human exposure, navigation and communication facilities/equipment, fuels and any existing EMR at the Port of Valdez may occur by the use of an XBR. Table 2.1.4-2 lists the maximum potential interference distances that define the ROI based on various subjects that could interact with the radar. Appendix B includes a general description of the health and safety resource area and a detailed discussion of the laws, regulations and standards concerning maritime safety and EMR.

3.10.5.2 Affected Environment

The Coast Guard 17th District MSO Valdez provides marine inspections, casualty investigations, fishing vessel inspections, harbor patrol, pollution response and facility contingency planning for Port Valdez and Prince William Sound. The MSO is composed of the Vessel Traffic Center and Public Works Department. The Vessel Traffic Center is staffed 24 hours per day, 7 days per week and tracks/coordinates marine traffic in Prince William Sound. The Vessel Traffic Center’s Vessel Traffic System utilizes radar, an Automated Dependent Surveillance Shipboard System, radio and other to obtain and disseminate information regarding vessel movement. The Center is supported by Vessel Traffic Center radar at Hinchinbrook Island, Naked Island, Potato Point and the Valdez Spit. The MSO Public Works Department oversees and maintains Coast Guard owned equipment and facilities, including the remote Vessel Traffic Center radar sites.

In accordance with State of Alaska and Federal oil spill prevention and response agreements and plans, every laden tanker is escorted from the Port to Hinchinbrook Entrance by an ocean going tug and an APSC Ship Escort/Response Vessel. One of the escort vessels serves as ice scout, keeping approximately one-half mile ahead of outbound tankers to assess ice hazards. Escort is also provided for empty inbound tankers during low visibility conditions, when ice is reported or when it has been 6 hours since an ice report was issued. Radar is one of the means by which the Ship Escort/Response Vessels assess ice conditions in the Sound. Ship Escort/Response Vessel personnel are trained in advanced spill response.

The Valdez Terminal maintains an Oil Spill Contingency Plan. Tankers are surrounded with containment booms as soon as they are berthed and are inspected hourly during the 18-hour loading for any sign of a leak or spill. Loading is monitored and controlled by the OCC via a series of satellite, cable and terrestrial microwave radio systems. The terminal is equipped with workboats, self-propelled skimmers, and containment booms and an oil spill response team is on duty at all times. Spills from a tanker not at berth or transiting from the terminal are covered
under the Prince William Sound Tanker Spill Prevention and Response Plan. All transiting tankers must have individual oil spill contingency plans that incorporates the Prince William Sound Tanker Spill Prevention and Response Plan. APSC provides initial response to any spill from a transiting tanker.

A commuter airline serves the Port of Valdez. Section 3.10.2 provides an overview of the airspace and airports in the Port of Valdez ROI.

### 3.10.6 TRANSPORTATION—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PORT OF VALDEZ

#### 3.10.6.1 Region of Influence

The ROI includes areas that may potentially be affected by the use of the Port of Valdez for the SBX, including the mooring sites as identified in section 2.3.1.10. Pier-side operations can be carried out for the SBX during limited time periods. Valdez does not maintain the pier capacity to commit pier-space year round for the SBX, which would yield to cruise ships. However, there are numerous mooring locations near the container dock for long-term operations. No requirements for aviation or railway transportation are anticipated and no impacts to those modes of transport are expected; consequently this section will predominately concern itself with ocean traffic, though roadway transportation is also addressed.

#### 3.10.6.2 Affected Environment

**Ocean Traffic**

Marine transportation plays an important role in the Prince William Sound area, including its role in shipping petroleum products from the Valdez Marine Terminal. The Port of Valdez is equipped with the highest level of marine infrastructure, accommodating interstate and international cargo receipt and shipment, while providing a minimum draft of 6 meters (20 feet). The Port of Valdez is an ice-free port with access to Interior Alaska, the U.S. Pacific Northwest, Northern Canada, and Pacific Rim trade routes. This deepwater port has containerized storage and containerized roll-on/roll-off and lift-on/lift-off capabilities, as well as access to the Richardson Highway, the Valdez Airport, and the AMHS. The Port of Valdez is among those in the Prince William Sound area providing facilities for the AMHS, which provides scheduled service to the City of Valdez, as well as Cordova, Seward, Whittier, and “whistlestop” service to Chenega Bay and the renowned Tatitlek. (U.S. Department of the Interior, Bureau of Land Management, 2002) The Port of Valdez is the southern terminus of the trans-Alaska oil
pipeline; supertankers navigate the deep, ice-free waters of Valdez Arm each day, handling more than 1.5 million barrels of crude oil (City of Valdez, 2002a).

The Valdez City Dock is a 183-meter (600-foot) wharf. The Valdez Container Terminal Dock is a 213-meter (700-foot) concrete floating dock; water depth at mean low tide is 15 meters (50 feet). This dock is designed as a multi-purpose berth to handle containerized, roll on/roll off, and lift on/lift off operations. (City of Valdez, 2002a)

Road Traffic
In Fairbanks, the Richardson Highway connects to the Steese Highway that follows the pipeline for 18 kilometers (11 miles) until the intersection with the Elliot Highway. In addition, approximately 284 secondary roads provide private access to the pipeline, pump stations, and airstrips. These highways, with the exception of the Dalton Highway, are typically asphalt-paved two-lane roads. In a populated center such as Fairbanks, more than two lanes may exist.

Except near Valdez and Fairbanks, traffic congestion is not a problem, although road maintenance activities may cause traffic delays. Annual ADT counts along the Richardson Highway vary significantly between Valdez and Fairbanks from approximately 300 to 22,400 vehicles per day, depending on location (see table 3.10.6-1). Traffic during the summer can be double the annual averages and is typically higher near the communities of Valdez, Glennallen, Delta Junction, and Fairbanks. (U.S. Department of the Interior, Bureau of Land Management, 2002)

3.10.7 UTILITIES—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PORT OF VALDEZ

3.10.7.1 Region of Influence
The ROI includes areas that may potentially be affected by the use of the Port of Valdez for the SBX, including the mooring sites as identified in section 2.3.1.10. Pier-side operations can be carried out for the SBX during limited time periods. Valdez does not maintain the pier capacity to commit pier-space year round for the SBX, which would yield to cruise ships. However, there are numerous mooring locations near the container dock for long-term operations.
3.10.7.2  Affected Environment

Energy

Copper Valley Electric Association, which provides electricity to the City of Valdez, derives much of its power from the 13-MW Solomon Gulch Hydroelectric Facility, owned by the Four Dam Pool Power Agency, and owns diesel plants in Glennallen and Valdez. Copper Valley Electric Association operates the hydroelectric plant, which is located in Valdez on Daysville Road; from here, units at all three generation facilities can be controlled. (Copper Valley Electric Association, Inc, 2003; Vacation Alaska.com, 2002) The Glennallen and Valdez plants are used for backup energy. The Valdez Diesel Plant houses three Fairbanks Morse 38D8 1/8 opposed piston units, three Enterprise DSR 46 units, and a trailer-mounted Solar Centaur turbine unit. The available generation capacity of this plant is 9.25 MW. (Copper Valley Electric Association, 2002) Currently, there is no electrical hookup at either of the two docks at Port of Valdez (Kinney, 2002).

Water

Valdez water is derived from four primary wells and is stored in two 2.8-million-liter (750,000-gallon) reservoirs before being piped for distribution throughout Valdez; over 95 percent of homes are fully plumbed, though many utilize individual wells. Water storage capacity is 8.48 million liters (2.24 million gallons). (Vacation Alaska.com, 2002) Over 6.8 million liters (1.8 million gallons) of water is provided daily to city residents (City of Valdez, 2002a). Water hookups are available at the Port of Valdez docks, which charge per 3,785-liter (1,000-gallon) units. This system is capable of servicing cruise ships of variable sizes, with records of typical demands ranging from 174,128 liters to 245,185 liters (46,000 gallons to 64,771 gallons). (Kinney, 2002)

Wastewater

The City of Valdez Wastewater Treatment Plant located on South Sawmill Road is capable of processing over 4.73 million liters (1.25 million gallons) of wastewater per day, with sewage deposited in a secondary treatment lagoon. Over 95 percent of homes are fully plumbed, though many utilize septic tanks. (Vacation Alaska.com, 2002) The average daily flow in 2001 was 3.56 million liters (0.94 million gallons) per day (U.S. Environmental Protection Agency, 2001b), but the Public Works Department of the City of Valdez cites current levels at the slightly lower rate of 3.3 million liters (0.87 million gallons) per day (City of Valdez, 2002b). Wastewater requirements at the Port of Valdez docks are handled by private contractor, and wastewater is trucked out as required, with levels on a case-by-case basis (Kinney, 2002).

Solid Waste

The Valdez Landfill, a Class 2 landfill operated by the City of Valdez on Glacier Haul Road, utilizes a bale fill system (Vacation Alaska.com, 2002). At the Port of Valdez docks, the City provides dumpsters to handle solid waste removal (Kinney, 2002).
3.10.8 VISUAL AND AESTHETIC RESOURCES—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PORT OF VALDEZ

Appendix B includes a description of visual and aesthetic resources and the analysis of the potential impacts from the Proposed Action.

3.10.8.1 Region of Influence

The ROI includes areas that may potentially be affected by the use of Port of Valdez for the SBX, including the mooring site identified in section 2.3.1.10.

3.10.8.2 Affected Environment

Essentially, the affected environment for Valdez, Alaska consists of the Port of Valdez and the surrounding areas of Prince William Sound. The Port of Valdez is primarily used to support the Trans-Alaska Pipeline which terminates at the Port of Valdez.

The average weather for Valdez consists of an annual temperature of 3°C (38°F), an annual precipitation of 163 centimeters (64 inches), an annual snowfall of 802 centimeters (316 inches), and approximately 16 days per year of heavy fog where visibility is less than 0.4 kilometer (0.25 mile).

Valdez is nestled among high mountain ranges that surround Prince William Sound. These ranges have an elevation of up to and exceeding 1,400 meters (4,600 feet).

Vegetation in and surrounding Valdez is classified as coastal forest which predominantly consists of evergreen forests coupled with deciduous forests in along the waterways and in disturbed areas. (Bureau of Land Management, 2002)

Facilities located in and around the Port of Valdez are primarily associated with the Trans-Alaska Pipeline. The city of Valdez maintains two hotels, two bed and breakfasts, a bank, and three recreational vehicle parks.

Those which may be affected by the Proposed Action visually include the sightseers and tourists, residents of Valdez and the surrounding areas, and those associated with the Trans-Alaska Pipeline.
3.11 BROAD OCEAN AREA (EXECUTIVE ORDER 12114)

Executive Order 12114, Environmental Effects Abroad of Major Federal Actions, represents the U.S. Government's exclusive and complete determination of the procedural and other actions to be taken by federal agencies to further the purpose of the NEPA, with respect to the environment outside the United States, its territories and possessions. This Executive Order enables responsible officials of federal agencies to be informed of pertinent environmental considerations and to take such considerations into account, with other pertinent considerations of national policy in making decisions regarding proposed actions. While based on independent authority, it furthers the purpose of the NEPA and the Marine Protection Research and Sanctuaries Act of 1972 (33 USC §§ 1401 et seq.; 16 USC 1431 et seq.) and the Deepwater Port Act of 1974, as amended (33 USC §§ 1501-1524) consistent with the foreign policy and national security policy of the United States.

This section describes the baseline conditions within the BOA that may be affected by the GMD ETR activities. The information contained in this section is summarized from the Theater Missile Defense Extended Test Range Supplemental Environmental Impact Statement-Eglin Gulf Test Range (U.S. Department of the Air Force, 1998b), Pacific Missile Range Facility Enhanced Capability Final Environmental Impact Statement (Pacific Missile Range Facility, Barking Sands, 1998), North Pacific Targets Program Environmental Assessment (U.S. Army Space and Missile Defense Command, 2001b), and the Long Range Air Launch Target Environmental Assessment (U.S. Department of Defense, Missile Defense Agency, 2002). These documents included environmental analysis of potential impacts from missile launches and other military actions in the Gulf of Mexico and the Central and North Pacific. As appropriate, additional information used to develop this section is referenced accordingly.

Airspace, biological resources, health and safety, and transportation were identified as resource areas with potential impacts in the BOA. Water quality and noise are included in the analysis, from the standpoint of potential impacts on marine life.

With the BOA being the ROI, there is no potential for impacts to air quality, cultural resources, land use, geology and soils, hazardous materials and hazardous waste, socioeconomics, utilities, visual and aesthetic resources, water resources, and environmental justice. Similarly, since the BOA is well removed from islands and population centers, no impacts to the human noise environment, socioeconomics, and utilities are anticipated. Impacts to air quality from similar missiles and mobile sources have been determined to be insignificant.

Region of Influence

The ROI includes all areas that would be potentially affected by GMD test activities beyond the territorial limits of the United States. This includes areas within the Gulf of Mexico, the Atlantic Ocean, and the Pacific Ocean that may be affected by the SBX travel and operations. The Gulf of Mexico ROI would be limited to areas for sea trials and initial full power testing of the SBX. The enroute ROI, from the Gulf of Mexico to the Pacific Ocean, would most likely follow the coast of South America toward Cape Horn, and include full power calibration and tracking along the route. The Pacific Ocean Area ROI occupies approximately 7.1 million square kilometers (2.1 million square nautical miles) in the central north Pacific Ocean, or approximately 4 percent of the Pacific Ocean’s total area. The average depth of the Ocean Area ROI is 3,932 meters (12,900 feet).
3.11.1 AIRSPACE—BROAD OCEAN AREA

Appendix B includes a general description of airspace.

3.11.1.1 Affected Environment

Controlled and Uncontrolled Airspace

The airspace beyond the 22.2-kilometer (12-nautical-mile) limit is in international airspace. For this reason, the procedures of the ICAO, outlined in ICAO Document 4444-RAC/501, Rules of the Air and Air Traffic Services, are followed in this airspace (International Civil Aviation Organization, 1996; 1997). ICAO Document 4444-RAC/501 is the equivalent air traffic control manual to the FAA Handbook 7110.65, Air Traffic Control. However, the ICAO is not an active air traffic control agency, and has no authority to allow aircraft into a particular sovereign nation’s Flight Information Region or Air Defense Identification Zone, and does not set international boundaries for air traffic control purposes. Rather, the ICAO is a specialized agency of the United Nations, whose objective is to develop the principles and techniques of international air navigation, and to foster planning and development of international air transport. FAA Air Traffic Service outside U.S. airspace is provided in accordance with Article 12, Rules of the Air, and Annex 11, Air Traffic Regulations and Air Traffic Services, of the ICAO Convention. The FAA acts as the United States’ agent for aeronautical information to the ICAO.

3.11.1.1.1 Gulf of Mexico

The Gulf of Mexico ROI is defined as the overwater area that would be potentially affected by the Proposed Action using portions of the international airspace over the Gulf of Mexico. This includes the entire northern Gulf of Mexico within the Houston, Jacksonville, and Miami ARTCCs, and the Houston and Miami Oceanic CTA/FIR (figure 3.11.1–1).

Special Use Airspace

Special use airspace occupies a significant portion of the Gulf of Mexico ROI. Much of the eastern part of the Gulf of Mexico ROI is occupied by the Eglin Water Test Area (EWTA) (figure 3.11.1-1). The Letter of Agreement between Jacksonville ARTCC, Miami ARTCC, Houston ARTCC, U.S. Navy Training Wing 6, and the Air Force Development Test Center defines the EWTA as “... all airspace in Warning Areas W-151, W-155B, W-168, W-174, W-470, and the airspace divided into five (5) areas ...” These are described in annexes to the agreement (U.S. Department of the Air Force, 1998b). EWTA 6 was added in 1996. The six EWTAs serve a similar function as Warning Areas, via the NOTAM system, providing airspace for hazardous aircraft flying operations including air-to-surface, air-to-air, and surface-to-air activities. Almost all of the EWTAs lie outside the 22.2-kilometer (12-nautical-mile) limit of the National Airspace System and include EWTAs 1, 2, 3, 4, 5, and 6. Other special use airspace in the eastern part of the ROI includes the Tortugas Military Operations Area, due west of Key West.

Special use airspace areas in the western part of the Gulf of Mexico ROI include Warning Area W-453 south of Mobile, Alabama; Warning Areas W-92, W-59, and W-147A/B south and southwest of New Orleans, Louisiana; and Warning Areas W-147C/D/E, W-228, and W-602 off the Texas coast (figure 3.11.1-1).
Special Use Airspace Over the Gulf of Mexico

Figure 3.11.1-1
En Route Airways and Jet Routes

The Gulf of Mexico ROI airspace is crossed by numerous airways and jet routes, especially the important Gulf Route 26 and J-58-86 jet route (figure 3.11.1-2). An airway is a control area, or portion thereof, established in the form of a corridor up to but not including 5,486.4 meters (18,000 feet) mean sea level, the centerline of which is defined by radio navigational aids. The routes are referred to as Colored Federal Airways, or very high frequency omni-directional range airways over land, and A routes, or low frequency/medium frequency airways over water, with numbering to identify the designated route. A jet route is a route designed to serve aircraft operations from 5,486.4 meters (18,000 feet) mean sea level up to and including FL 450. The jet routes are referred to as J routes with numbering to identify the designated route.

Figure 3.11.1-3 presents an Aircraft Situation Display of the Gulf of Mexico ROI on Tuesday, 7 October 1997, at 9:30 a.m. (Martin, 1997). It represents a snapshot of all aircraft in the air at that time, taken from the radar at Jacksonville ARTCC. Clearly, the number of aircraft actually en route would vary by time of day, and also by week, month, or season, but the snapshot does give a representative account of the number of aircraft in the air over the Gulf of Mexico at a moment in time. Some 32 aircraft are in the overwater ROI. The snapshot also illustrates the relative low density of en route air traffic over the Gulf of Mexico, compared to the much higher density of air traffic over the mainland, and even along the Atlantic coast. Even so, most of the ROI air traffic in this snapshot is between the central and south Florida and New Orleans, Louisiana, area (figure 3.11.1-2). Approximately 500 aircraft each day use J58-86 or GR26 to transit the Gulf of Mexico between St. Petersburg/Sarasota, Florida, and New Orleans/Leesville, Louisiana. Of these, approximately 325, or 65 percent, operate during daylight hours (7:00 a.m. to 9:00 p.m. Eastern Daylight Time) (U.S. Department of the Air Force, 1998b). This translates into a nominal average of 23 aircraft per hour, assuming an even hourly distribution.

A new jet route across the northeastern Gulf of Mexico has been proposed by the FAA and agreed to by the U.S. Air Force. Although it has not yet been formalized, the route would accommodate the increased traffic across the Gulf of Mexico that is expected with the full implementation of the North American Free Trade Agreement. It would be an extension of the existing A-758 jet route northeast directly into Tampa Bay. This new route would cut across the northwest corner of W-168A. West of the new route, W-168A would still be used at 8,534.4 meters (28,000 feet) above ground level and below. Commercial aircraft would be assigned 8,839.2 meters (29,000 feet) above ground level and above (U.S. Department of the Air Force, 1998b).

Air traffic in the ROI is managed by the Houston, Jacksonville, and Miami ARTCCs and the Houston and Miami Oceanic CTA/FIRs.

The special use airspace areas in the Gulf of Mexico ROI are managed or scheduled by several organizations. The EWTA, the largest special use airspace complex in the ROI, is managed by Eglin AFB under a letter of agreement among Jacksonville ARTCC, Miami ARTCC, Houston ARTCC, U.S. Navy Training Wing 6, and the Air Force Development Test Center (U.S. Department of the Air Force, 1998b). There are some overlaps in airspace assignment, notably that Warning Area W-155B occupies some of Eglin AFB EWTA-1, and is used on a coordinated basis. Additionally, several portions of airspace adjacent to or overlapping these areas are used by Eglin AFB assigned units, but are managed by other organizations. Fleet area control and surveillance facility, NAS Pensacola, functions as the controller for the airspace assigned to their units.

- Aircraft

Aircraft Situation Display of the Gulf of Mexico

Scale

0 140 280 kilometers

0 87 174 miles

When a requirement exists for use of airspace beyond the Warning Areas and above FL 240 (7,315.2 meters [24,000 feet]) that would impact Gulf Route 26, the airspace may not be scheduled for longer than a 4-hour block of time when the requirement is for a hazardous use of the airspace (such as missiles or drones). At FL 240 and below, it may not be scheduled for longer than 12 hours. There must be a 3-hour period between blocks of scheduled airspace (U.S. Department of the Air Force, 1998b).

3.11.1.1.2 En Route Gulf to Pacific

Special Use Airspace

Warning Areas are established in international airspace to contain activity that may be hazardous, and to alert pilots of nonparticipating aircraft to the potential danger. Warning areas along the route to the Pacific are shown on figure 3.11.1-4.

En Route Airways and Jet Routes

En route high altitude jet routes are shown on figure 3.11.1-4.

3.11.1.3 Pacific Ocean

The Pacific Ocean ROI includes the overwater area that would be potentially affected by the Proposed Action using portions of the international airspace over the northern Pacific Ocean. This area includes the Los Angeles, Oakland, Anchorage, and Seattle ARTCCs.

Special Use Airspace

Domestic Warning Areas and Warning Areas are established in international airspace to contain activity that may be hazardous, and to alert pilots of nonparticipating aircraft to the potential danger (figure 3.11.1-5). The special use airspace PMRF includes Warning Area W-188 north of Kauai, and Warning Areas W-189 and W-190 north of Oahu. A Temporary Operating Area extends north and west of PMRF approximately 2,200 kilometers (1,367 miles). There are also numerous warning areas along the U.S. Pacific coastline.

En Route Airways and Jet Routes

Figure 3.11.1-6 shows en route high altitude jet routes.

The overseas high-altitude jet routes cross the southern part of the airspace ROI via nine CAE corridors off the California coast. These corridors can be opened or closed at the request of a user in coordination with the FAA. A Military Operations Area exists between users and the FAA to stipulate the conditions under which the CAEs can be closed to civil traffic. Under most circumstances, at least one CAE must remain available for use by general aviation and commercial air carriers.

The overseas high-altitude jet routes cross the northern part of the airspace ROI via five corridors off the California coast (see figure 3.11.1-6). These corridors and associated jet routes continue northwest to Alaska and then southwest to the orient.

GMD ETR Final EIS
Figure 3.11.1-6

High Altitude Jet Routes

As an alternative to aircraft flying above 8,839 meters (29,000 feet) following the published jet routes (figure 3.11.1-6), the FAA is gradually permitting aircraft to select their own routes as alternatives. This Free Flight program is an innovative concept designed to enhance the safety and efficiency of the National Airspace System. The concept moves the National Airspace System from a centralized command-and-control system between pilots and air traffic controllers to a distributed system that allows pilots, whenever practical, to choose their own route, and file a flight plan that follows the most efficient and economical route (Federal Aviation Administration, 1998).

Free Flight is already underway, and the plan for full implementation will occur as procedures are modified, and technologies become available and are acquired by users and service providers. This incremental approach balances the needs of the aviation community and the expected resources of both the FAA and the users. Advanced satellite voice and data communications are being used to provide faster and more reliable transmission to enable reductions in vertical, lateral, and longitudinal separation, more direct flights and tracks, and faster altitude clearances (Federal Aviation Administration, 1998). With full implementation of this program, the amount of airspace in the ROI that is likely to be clear of traffic will decrease as pilots, whenever practical, choose their own route and file a flight plan that follows the most efficient and economical route, rather than following the published jet routes.

In addition to the IFR high-altitude jet routes and low-altitude airways used by commercial aircraft, general aviation aircraft fly unrestricted in accordance with VFR within the Military Operations Areas below FL 180.

3.11.2 BIOLOGICAL RESOURCES—BROAD OCEAN AREA

Marine biology of the BOA consists of the animal and plant life that lives in and just above the surface waters of the sea and its fringes, the salient physical and chemical properties of the ocean, biological diversity, and the characteristics of its different ecosystems or communities.

3.11.2.1 Affected Environment

3.11.2.1.1 Gulf of Mexico

Vegetation

Marine vegetation such as seagrasses and benthic (bottom-dwelling) algae are attached to the bottom and are dependent on light. Therefore, they generally are found in shallow, sunlit depths of less than 18 meters (60 feet). Within the eastern Gulf of Mexico, the most common seagrasses are turtle grass, shoal grass, and manatee grass. Less common species include stargrass and paddle grass. Seagrass communities are further discussed below under sensitive habitats. (U.S. Department of the Air Force, 1998b)

Wildlife

The bottlenose dolphin is the most common marine mammal in south Florida waters and feeds on fish in seagrass beds. Fish representative of species common to the Gulf of Mexico along the north Florida shore include skipjack herring, sea catfish, spotfin mojarra, Atlantic croaker, Gulf flounder, bluefish, and Florida pompano. Fish species that are representative of species common to the Gulf of Mexico along the south Florida shore include dolphin, red grouper,
hogfish, red snapper, black grouper, cobia, king mackerel, Spanish mackerel, and greater amberjack. (U.S. Department of the Air Force, 1998b)

Pelagic seabirds can be found in the Gulf of Mexico throughout the year. Numerous migratory or nonresident birds cross the Gulf of Mexico during summer and fall migrations. Approximately two thirds of the breeding birds of the eastern United States migrate to Central and South America, Mexico, and the Caribbean. The migratory route for many of these species includes the Gulf of Mexico. Fall migration occurs between September and October; spring migration peaks in late April. Some of the commonly observed migratory birds within the eastern Gulf of Mexico are blue-winged teal, ruby-throated hummingbird, upland sandpiper, cattle egret, black tern, storm petrel, and mourning dove. (U.S. Department of the Air Force, 1998b)

**Threatened and Endangered Species**

*Species with Federal Status Known to Occur in the Gulf of Mexico*

The Florida manatee (*Trichechus manatus*) is a federal and state endangered species. Most of the manatees are located along the Atlantic shore of Florida, with smaller numbers occurring in the Florida Keys and along the Gulf of Mexico.

The Gulf sturgeon (*Acipenser oxyrhinchus desotoi*) is a federally threatened fish that migrates from saltwater into large coastal rivers to spawn and spend the warm months. It is found predominately in the northeastern Gulf of Mexico from the Mississippi Delta east to Tampa Bay. This species is almost depleted throughout most of its range. Analysis of stomach contents of the sturgeon suggests that this species could feed as far as 32 kilometers (20 miles) offshore. (U.S. Department of the Air Force, 1998b)

Five species of sea turtles occur in the Gulf of Mexico (table 3.11.2-1). The hawksbill is seen regularly in the waters near the Florida Keys. The loggerhead is the most commonly seen sea turtle in the southeastern United States and may be found near underwater structures and reefs. Adult Kemp’s Ridley sea turtles (*Lepidochelys kempii*) are usually confined to the Gulf of Mexico and have the most restricted distribution of any sea turtle. Green sea turtles occur throughout the Gulf of Mexico, but appear to be particularly common in the southern Gulf of Mexico region. Green sea turtles are frequently found in the Gulf of Mexico in areas where there is an abundance of seagrass. The leatherback sea turtle, a migratory species that nests in the tropics, has a world-wide distribution (U.S. Department of the Air Force, 1996). Loggerhead and leatherback sea turtles are the most frequently sighted species.

Most sea turtles in the Gulf of Mexico typically occur in relatively shallow nearshore waters close to coastal feeding and nesting areas. Exceptions are hatchlings that are likely to be found near Sargassum rafts and the leatherback that is known to prefer deeper water (U.S. Department of the Air Force, 1998b).

E – Endangered  
T – Threatened  
SC – Species of Concern  

Six endangered species of whales have the potential to occur in the Gulf of Mexico: the fin whale, Sei whale (*Balaenoptera borealis*), right whale (*Eubalaena glacialis*), humpback whale, blue whale (*Balaenoptera musculus*), and sperm whale.

**Sensitive Habitats**

Seagrass habitats have been declining, according to recent studies, mainly in highly developed, industrialized, or populated areas. Most causes of decline are related to habitat alteration, such as dredging, wetland filling, and removal of submergent vegetation. Boating has also contributed to the direct destruction of seagrass habitat. Much of the seafood consumed in this country is dependent on seagrass community food chains. Seagrass beds serve as nurseries for juveniles of a variety of fin and shellfish. Seagrasses also stabilize sediments by reducing water velocity and forming a complex matrix that binds sediments and retards erosion (U.S. Department of the Air Force, 1998b).

Extensive coral reefs occur offshore of the Florida Keys archipelago. Coral reefs also extend into the Gulf of Mexico from Key West to the Content Keys. Coral reefs thrive in relatively warm, clear waters with normal marine salinities. Corals derive nutrition from algae that require light. Most reef corals are colonial organisms. Two species of fire corals, or branching corals, occur on Florida reefs: the bladed fire coral and the crenulated fire coral. (U.S. Department of the Air Force, 1998b)
Octocorals, which include sea whips, sea plumes, sea fans, gorgonians, and soft corals, are found on most Florida Keys reefs. Sixty-three species of stony corals have been identified in the Florida Keys. Stony corals with octocorals form the reef canopy. Branching corals along with the reef framework provide shelter for fish. The coral canopy provides shelter from larger predators that occur along the reef margin. (U.S. Department of the Air Force, 1998b)

Several areas or habitats in the Gulf of Mexico are afforded special protection or recognition. Aquatic preserves are state-owned submerged lands with outstanding biological or scientific features. These lands are managed to ensure that development activities are compatible with goals of resource protection. The Gulf Islands National Seashore was established in 1971 to preserve and maintain historic and natural features. It is composed of three mainland tracts in Pensacola and Gulf Breeze, Florida, and Ocean Springs, Mississippi, and 241.4 kilometers (150 miles) of islands from Ship Island, Mississippi, to Santa Rosa Island. (U.S. Department of the Air Force, 1998b)

The Florida Keys National Marine Sanctuary consists of 7,251 square kilometers (2,800 square miles) of nearshore waters extending from just south of Miami to the Dry Tortugas. The Dry Tortugas were declared a National Park in 1992 and have the least disturbed coral reef system in the continental United States. The Florida Middle Grounds contains the principal hard-bottom in the United States and is the northernmost extent of coral reefs in the Gulf of Mexico. This live bottom area supports a variety of species similar to typical Caribbean reef communities. The Florida Middle Grounds are sensitive to environmental change. (U.S. Department of the Air Force, 1998b)

3.11.2.1.2 En Route Gulf of Mexico to Pacific Ocean

The route from the Gulf of Mexico to the Pacific Ocean would most likely follow the coast of South America toward Cape Horn since the vessel would not be able to pass through the Panama Canal. The Atlantic Ocean, the second largest of the world’s five oceans after the Pacific Ocean, covers an area of approximately 77 million square kilometers (30 million square miles). The equator divides the Atlantic into the North Atlantic Ocean and the South Atlantic Ocean. The southern Atlantic has a counterclockwise warm water current system. Natural resources in this region include oil and gas fields, fish, marine mammals (seals and whales), and sand and gravel aggregates. Endangered marine species include the manatee, seals, sea lions, sea turtles, and whales. (Central Intelligence Agency, Directorate of Intelligence, 2002a)

3.11.2.1.3 Pacific Ocean

The general composition of the ocean includes water, sodium chloride, dissolved gases, minerals, and nutrients. These characteristics determine and direct the interactions between the seawater and its inhabitants. The most important physical and chemical properties are salinity, density, temperature, pH, and dissolved gases. For oceanic waters, the salinity is approximately 35 parts of salt per 1,000 parts of seawater.

Most organisms have a distinct range of temperatures in which they may thrive. A greater number of species live within the moderate temperature zones, with fewer species tolerant of extremes in temperature. Most areas of the Pacific maintain a temperature of 4°C (39.2°F).
Surface seawater often has a pH between 8.1 and 8.3 (slightly basic), but generally is very stable with a neutral pH. The amount of oxygen present in seawater will vary with the rate of production by plants, consumption by animals and plants, bacterial decomposition, and surface interactions with the atmosphere. Most organisms require oxygen for their life processes. Carbon dioxide is a gas required by plants for photosynthetic production of new organic matter. Carbon dioxide is 60 times more concentrated in seawater than it is in the atmosphere.

Coastal Zone
The coastal zone is defined as that area which typically extends from the high tide mark on the land to the gently sloping, relatively shallow edge of the continental shelf, the submerged part of the continents. This may differ from the way the term coastal zone is defined in the Hawaii Revised Statutes, Chapter 205A, Coastal Zone Management.

Although it makes up less than 10 percent of the ocean’s area, the coastal zone contains 90 percent of all marine species. The sharp increase in water depth at the edge of the continental shelf separates the coastal zone from the offshore zone. (Pacific Missile Range Facility, Barking Sands, 1998)

The coastal zone includes several different ecosystems including coral reefs, estuaries, and coastal wetlands. There are no estuaries or coastal wetlands in the BOA ROI. Coral reefs are the world’s oldest and most diverse and productive ecosystems—the marine equivalent of tropical rain forests. Species diversity associated among reef communities is probably the highest of all biological habitats in the sea. (Pacific Missile Range Facility, Barking Sands, 1998)

Ocean Zones
Classification of the Pacific Ocean zones is based upon depth and proximity to land. Using this methodology, there are four major divisions or zones in the ocean: the littoral zone, the coastal zone, the offshore zone, and the pelagic zone. Spanning across all zones is the benthic environment, or sea floor. This section discusses the pelagic zone and the benthic environment.

The pelagic zone is commonly referred to as the open ocean. The organisms that inhabit the open ocean typically do not come near land, continental shelves, or the seabed. Approximately 2 percent of marine species live in the open ocean.

The bottom of the sea floor is known as the benthic area. It comprises 98 percent of the species of animals and plants in the ocean. Less than 1 percent of benthic species live in the deep ocean below 2,000 meters (6,562 feet).

Biological Diversity
Marine life ranges from microscopic one-celled organisms to the world’s largest animal, the blue whale. Marine plants and plant-like organisms can live only in the sunlit surface waters of the ocean, the photic zone, which extends to only about 101 meters (330 feet) below the surface. Beyond the photic zone, the light is insufficient to support plants and plant-like organisms. Animals, however, live throughout the ocean from the surface to the greatest depths.
The organisms living in pelagic communities may be drifters (plankton) or swimmers (nekton). The plankton consists of plant-like organisms and animals that drift with the ocean currents, with little ability to move through the water on their own. The nekton consists of animals that can swim freely in the ocean, such as fish, squids, and marine mammals. Benthic communities are made up of marine organisms, such as kelp, sea grass, clams, and other species that live on or near the sea floor.

**Threatened and Endangered Species**

Species identified as threatened or endangered that exist in the Ocean Area ROI, listed in table 3.4.2-1 include the sei whale, blue whale, fin whale, humpback whale, sperm whale, Hawaiian monk seal, loggerhead sea turtle, green sea turtle, leatherback sea turtle, hawksbill sea turtle, and olive ridley sea turtle.

**Northwestern Hawaiian Islands Coral Reef Ecosystem Reserve**

In order to “ensure the comprehensive, strong, and lasting protection of the coral reef ecosystem and related marine resources and species (resources) of the Northwestern Hawaiian Islands,” Executive Order 13178, *Northwestern Hawaiian Islands Coral Reef Ecosystem Reserve*, created the reserve so named in December 2000. Executive Order 13196, *Final Northwestern Hawaiian Islands Coral Reef Ecosystem Reserve*, amended Executive Order 13178 by finalizing several of its provisions.

The reserve lies to the northwest of the main islands of the Hawaiian chain. The Reserve includes submerged lands and waters of the Northwestern Hawaiian Islands, extending approximately 2,220 kilometers (1,200 nautical miles) long and 185 kilometers (100 nautical miles) wide. The Reserve is adjacent to and seaward of the seaward boundaries of the State of Hawaii and the Midway Atoll National Wildlife Refuge. The Reserve also includes the Hawaiian Islands National Wildlife Refuge to the extent that it expands beyond the seaward boundaries of the State of Hawaii. The seaward boundary of the Reserve is 93 kilometers (50 nautical miles) from the approximate geographical centerline of Nihoa, Necker, French Frigate Shoals, Gardner Pinnacles, Maro Reef, Laysan, Lisianski, Pearl and Hermes Reef, Midway Atoll, and Kure (figure 3.11.2-1). (Federal Register, 2000a)

**3.11.3 HEALTH AND SAFETY—BROAD OCEAN AREA**

**3.11.3.1 Affected Environment**

The U.S. marine transportation system encompasses a national and global network of navigable ocean, lake, river, and inland waterway routes; the vessels that carry waterborne commerce; a complex of ports and terminals serving as intermodal points of transfer between the water system and the land-based transportation modes; ship operators; an extensive supplier base; and shipboard, shipyard, and longshore labor forces.

The International Maritime Organization (IMO) is a specialized agency of the United Nations, whose objective is to develop and facilitate the general adoption of the highest practicable standards in matters of ship safety, training, operation, construction, certification, efficiency of navigation, and pollution prevention and control. The Maritime Safety Committee is IMO’s senior technical body on safety-related matters.
Northwestern Hawaiian Islands Coral Reef Ecosystem Reserve

EXPLANATION

PMRF = Pacific Missile Range Facility

Northwestern Hawaiian Islands Coral Reef Ecosystem Reserve

Open Ocean

Figure 3.11.2-1

GMD ETR Final EIS
IMO has also developed and adopted international collision regulations and global standards for seafarers, as well as international conventions and codes relating to search and rescue, the facilitation of international maritime traffic, load lines, the carriage of dangerous goods, pollution and tonnage measurement.

The Act to Prevent Pollution from Ships (33 USC §§ 1901 et seq.) was amended by the Marine Plastic Pollution Research and Control Act of 1987, which implemented the provisions of Annex V, Special Areas, of Garbage Discharges for Navy Ships into the International Maritime Convention for the Prevention of Pollution From Ships (relating to garbage and plastics). Annex V and the regulations implementing it apply to all vessels, whether seagoing or not, regardless of flag, on the navigable waters of the United States and in the exclusive economic zone of the United States. It applies to U.S. flag vessels wherever they are located.

Under the regulations implementing the Act to Prevent Pollution from Ships as amended by the Marine Plastic Pollution Research and Control Act, the discharge of plastics, including synthetic ropes, fishing nets, plastic bags, and biodegradable plastics, into the water is prohibited. Discharge of floating dunnage, lining, and packing materials is prohibited in the navigable waters and in areas offshore less than 46.3 kilometers (25 nautical miles) from the nearest land. Food waste or paper, rags, glass, metal, bottles, crockery and similar refuse cannot be discharged in the navigable waters or in waters offshore inside 22.2 kilometers (12 nautical miles) from the nearest land. Finally, food waste, paper, rags, glass, and similar refuse cannot be discharged in the navigable waters or in waters offshore inside 5.6 kilometers (3 nautical miles) from the nearest land. There are some exceptions for emergencies. Under the Act to Prevent Pollution from Ships, the definition of ship includes fixed or floating platforms. There are separate garbage discharge provisions applicable to these units. For these platforms, and for any ship within 500 meters (1,640 feet) of these platforms, disposal of all types of garbage is prohibited. Additionally, all manned, oceangoing U.S. flag vessels of 12.2 meters (40 feet) or more in length engaged in commerce, and all manned fixed or floating platforms subject to the jurisdiction of the United States, are required to keep records of garbage discharges and disposals (International Year of the Ocean, 1998a). Appendix B provides additional the laws, regulations and standards concerning maritime safety and EMR.

The WorldWide Navigational Warning Service is a worldwide radio and satellite broadcast system for the dissemination of Maritime Safety Information to U.S. Navy and merchant ships. The WorldWide Navigational Warning Service provides timely and accurate long range and coastal warning messages promoting the safety of life and property at sea and Special Warnings that inform mariners of potential political or military hazards that may affect safety of U.S. shipping. The world is divided into 16 Navigational Areas (NAVAREAs) for global dissemination of Maritime Safety Information. National Imagery and Mapping Agency is the coordinator of NAVAREAs IV and XII and is staffed 24 hours a day, 365 days a year. NAVAREA IV broadcasts cover the waters contiguous to North America from the Atlantic coast eastward to 35°W and between latitudes 7°N and 67°N, whereas NAVAREA XII broadcasts cover the waters contiguous to North America extending westward to the International Date Line and from 67°N to the equator east of 120°W, south to 3°25’S, then east to the coast.

Management of U.S. ports and its waterways system is spread among various federal agencies and stakeholders exercising specific authorities (International Year of the Ocean, 1998b). For example, the Department of Transportation Act (49 USC 101, et seq.) gives the DOT the responsibility to oversee the national transportation system. Other authorities relevant to marine
transportation can be found in USC 14, 16, 19, 33, 46 and 49 (International Year of the Ocean, 1998b). The primary maritime organizations within the DOT are the U.S. Coast Guard and the Maritime Administration.

The U.S. Coast Guard serves as Vice Chair to the National Response Team which chaired by the EPA. The National Response Center serves as the sole national point of contact for reporting all oil, chemical, radiological, biological, and etiological discharges into the environment anywhere in the United States and its territories. The National Response Team, along with Regional Response Teams, is the federal component of the National Response System, which responds to emergency discharges of oil and releases of chemicals.

The U.S. Coast Guard also acts as the United States’ agent for maritime information to the IMO.

3.11.3.1.1 Gulf of Mexico

The Gulf of Mexico ROI is defined as the overwaters, as well as the areas extending from the sea surface to the ocean floor that could be potentially affected by the Proposed Action, including the deployment/use of an XBR. The ROI includes the entire northern Gulf of Mexico within the ports of Tampa, Florida; Mobile, Alabama; New Orleans and Lake Charles, Louisiana; and Beaumont, Houston, Galveston, and Corpus Christi, Texas. The ROI for health and safety is based on the area where effects to human exposure, navigation and communication facilities/equipment (military and nonmilitary), fuels, and any existing EMR using portions of the international waters off the Gulf of Mexico could occur.

The ROI for EMR human health effects includes an area up to 85 meters (280 feet) from the SBX platform. Potential interference distances for certain electronic equipment and civilian aircraft includes an area up to 9.5 kilometers (5.9 miles) from the SBX platform for a half populated array and 19 kilometers (11.8 miles) for a fully populated array. Appendix B includes a general description of the health and safety resource area and a detailed discussion of the laws, regulations, and standards concerning maritime safety and EMR.

Section 3.11.1 provides a discussion of potentially affected special use airspace occupying the Gulf of Mexico. Section 3.11.4 provides a detailed discussion of seaports, shipping lanes and transportation issues. There are approximately 4,021 producing oil platforms located within the ROI. (Mineral Management Services, 2001)

The U.S. Coast Guard Atlantic Area Districts 7 (Florida) and 8 (Louisiana) serve the Gulf of Mexico ROI. The U.S. Coast Guard coordinates with and is supported by numerous organizations and authorities utilizing the Gulf Coast ROI including, but not limited to, Eglin AFB, NAS Pensacola, and the Military Sealift Command (U.S. Navy).

3.11.3.1.2 En Route Gulf of Mexico to Pacific Ocean

Warning Areas are established in international airspace and waters to contain activity that may be hazardous, and to alert pilots and captains of nonparticipating vessels to the potential danger. Specific Use Airspace and Air Routes over the Gulf of Mexico and the Pacific Ocean are shown on figure 3.11.1-4.
3.11.3.1.3 Pacific Ocean

The affected health and safety environment for the Pacific Ocean Area is described in detail within each potential range or PSB location in terms of its principal attributes, namely, range control procedures and verification of Ocean Area clearance procedures.

The Pacific Ocean ROI is defined as the overwaters, as well as the areas extending from the sea surface to the ocean floor that could be potentially affected by the Proposed Action, including the deployment/use of an XBR. The ROI occupies the central north Pacific Ocean. A detailed discussion of airspace, jet routes, seaports and shipping lanes occupying the Pacific Ocean is provided in section 3.11.1.1.3.

The U.S. Coast Guard Pacific Area Districts 11 (California), 14 (Hawaii) and 17 (Alaska) serve the Pacific Ocean ROI. Warning Areas are established in international airspace and waters to contain activity that may be hazardous, and to alert pilots and captains of nonparticipating vessels to the potential danger.

3.11.4 TRANSPORTATION—BROAD OCEAN AREA

Appendix B includes a general description of transportation.

The potential transportation issue related to the proposed activities is that of marine shipping. Marine shipping refers to the conveyance of freight, commodities, and passengers via mercantile vessels.

3.11.4.1 Affected Environment

3.11.4.1.1 Gulf of Mexico

Intracoastal Waterway

A substantial amount of domestic waterborne commerce along the Gulf Coast does not use open Gulf of Mexico waters. For transportation commodities, the Gulf Coast Intracoastal Waterway is the primary route; it is estimated that 40 percent of the world’s commerce passes within 1.5 days’ sailing time of the port of Key West (U.S. Department of the Air Force, 1998b).

Primary canals in the Gulf Coast Intracoastal Waterway include the New Orleans-Rigolet Cut, the Port-Arthur-Corpus Christi Channel, and the Inner Harbor Navigational Canal at New Orleans (U.S. Department of the Air Force, 1998b).

Commerce in the Gulf Coast Intracoastal Waterway has grown appreciably over the years, from 5.978 billion kilograms (6.59 million tons) in 1938 to 91.625 kilograms (101 million tons) in 1985 (U.S. Department of the Air Force, 1998b).

Within the ROI, 1995 total tonnage (including domestic coastwise tonnage) for the Gulf Coast Intracoastal Waterway was 107.05 billion kilograms (118.0 million tons); this was an increase of 0.3 percent over 1994 (U.S. Department of the Air Force, 1998b). For this same period, 3.688 billion kilograms (4.065 million tons) were transported between Apalachee Bay and Panama City; 6.94 billion kilograms (7.651 million tons) were transported from Panama City to
Pensacola; and 10.002 billion kilograms (11.025 million tons) were transported from Pensacola to Mobile Bay, Alabama (U.S. Department of the Air Force, 1998b). Commodities shipped included coal, petroleum, chemical products, fuels, and manufactured goods.

Based upon March 1997 estimates, this total decreased slightly by 1.8 percent to 105.051 billion kilograms (115.8 million tons) in 1996. This averages to approximately 10.9 percent of the internal U.S. waterways’ national domestic total for the 2 years. (U.S. Department of the Air Force, 1998b)

Gulf Shipping Lanes

Figure 3.11.4-1 represents a graphical representation of ships’ location within the Gulf of Mexico at a single point in time during 1997 (4,786 locations are presented). The major shipping lanes will normally have two or more vessels track to its next port of call throughout the day.

Table 3.11.4-1 provides the average number of ships in the Gulf of Mexico ports during 1994-1995.

Port to port travel within the Gulf of Mexico accounts for approximately 31 percent of the tank ships and 36 percent of the cargo ships leaving American ports. About 80 percent of the tank ships and 70 percent of the cargo ships leaving Mexican ports travel to other ports in the region. Major commodities shipped between ports in the region include crude oil, iron and steel products, iron ore, industrial and agricultural chemicals, coal, marine shells, sand, gravel, containerized cargo (such as processes food and equipment), and refined petroleum products (U.S. Department of the Air Force, 1998b).

Some 61 percent of the vessels entering and leaving the region move through the Florida Straits (U.S. Department of the Air Force, 1998b). This traffic passes back and forth under EWTAs 1, 2, 3, 4, 5, and 6 before converging under Warning Area 174 (Navy) to enter or exit the Gulf of Mexico. The remaining vessels travel through the Yucatan Channel and pass under EWTAs 1, 2, and 4.

Density of Shipping - Single Point in Time

Figure 3.11.4-1
The Gulf of Mexico has 490 public and private seaports with a total of 787 berths, accounting for 25.6 percent of the Nation’s total. Seven of the top ten U.S. ports are located in the Gulf region, testament to its importance in U.S. commerce. For 1995, the Port of South Louisiana (ranked first in U.S. port tonnage) handled 26.2 billion kilograms (28.87 million tons) of imported goods and 62.3 billion kilograms (68.64 million tons) of exports (table 3.11.4-2) (U.S. Department of the Air Force, 1998b).

Source: U.S. Department of the Air Force, 1998b

Fifteen of the top 50 U.S. ports for non-containerized materials such as coal, petroleum, food, and farm products are in the Gulf of Mexico.

3.11.4.1.2 En Route from Gulf of Mexico to the Pacific Ocean

The enroute ROI, from the Gulf of Mexico to the Pacific Ocean, would most likely follow the coast of South America toward Cape Horn.

The transit period would permit opportunities for testing, including full power calibration and tracking along the route. For periodic testing, the SBX would stop at predetermined locations during transit. The appropriate NOTMARs and NOTAMs would be issued and testing would ensue.

The SBX with retractable thrusters would have a 15.2-meter (50-foot) draft (during transit) and a 26- to 28-meter (85.3- to 91.8-foot) draft during operations. Because most harbors do not have the necessary depth to accommodate the SBX, even with retractable thrusters, it may not enter any port facilities after it leaves its assembly point in the Gulf of Mexico. More than one escort ship may accompany the SBX during its transit around South America and during testing.

Established shipping routes would be utilized during this 7-month test trip.
3.11.4.1.3 Pacific Ocean

The northern Pacific is an important commercial seaway, carrying a substantial proportion of the United States’ trade in raw materials and finishing products. In 1996, about 21 percent of all commercial vessels importing and exporting goods to and from the United States to 30 ports departed from, or were bound for, ports on the U.S. Pacific seaboard (Pacific Missile Range Facility, Barking Sands, 1998). The large majority of these vessels crossed the northern Pacific Ocean, to and from the large trading ports of Asia.

There are no regulations or directions obliging commercial vessels to ply specific cross-ocean lanes. Once it has left the navigation lanes leading out to the open sea, the majority of shipping will follow the course of least distance between two ports.

A composite “snapshot” of shipping in the Pacific, generated from satellite data for the busiest months of the year, is shown in figure 3.11.4-2. It shows the number of ships traveling across the northern Pacific in August 1997, with each ship identified and located once. The figure includes cargo vessels, tankers, passenger ships, and fishing vessels, and characterizes the random nature of commercial shipping movements in the northern Pacific.

The data shows that, while there is a general adherence to particular routes (such as the great circles of latitude between the United States to Asian ports), commercial vessels plot a diverse range of courses across the northern Pacific. This was confirmed by the National Imagery and Mapping Agency, which stated that it no longer published shipping routes for the northern Pacific for precisely this reason.

3.12 ENVIRONMENTAL JUSTICE

Executive Order 12898, *Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations*, was issued by President Clinton on 11 February 1994. Objectives of the Executive Order as it pertains to this EIS include development of federal agency implementation strategies; identification of minority and low-income populations where proposed federal actions have disproportionately high and adverse human health and environmental effects; and participation of minority and low-income populations. Accompanying Executive Order 12898 was a Presidential Transmittal Memorandum, which referenced existing Federal statutes and regulations to be used in conjunction with the Order. The memorandum addressed the use of the policies and procedures of NEPA. Specifically, the memorandum indicated that “each Federal agency shall analyze the environmental effects, including human health, economic and social effects, of Federal actions, including effects on minority communities and low-income communities, when such analysis is required by the NEPA 42 USC Section 4321 et. seq.”

An Environmental Justice impact would be a long-term health, environmental, cultural, or economic effect that has a disproportionately high and adverse effect on a nearby minority or low-income population, rather than all nearby residents. No adverse long-term impacts have been identified at any of the locations analyzed in this EIS. As such, there would be no disproportionately high and adverse human health or environmental effects on the minority or low-income populations that may be present in the vicinity of those locations. Thus, no Environmental Justice impacts are anticipated and additional Environmental Justice analysis will not be presented in this document.

Vandenberg AFB personnel suggested that Environmental Justice could be an issue if the potential exists for disproportionate effects on local Native Americans from the proposed project. However, initial analysis of the Environmental Justice issues, with respect to Chumash Indian uses of cultural areas in the vicinity of the proposed project locations, indicate that there should be no disproportionate impacts. Chumash use of the areas in question should be affected no more than that of other groups who access the base for recreation, fishing, etc. Furthermore, the proposed project requires only infrequent closures of the areas in question. Therefore, Environmental Justice is not an issue warranting in-depth analysis at Vandenberg AFB.

This chapter describes the potential environmental consequences associated with each location that may be affected by the Proposed Action, action alternatives, and the No Action Alternative along with the identification of potential cumulative impacts and mitigation measures. To assess the potential for and significance of environmental impacts from the proposed program activities, a list of activities was developed (chapters 1.0 and 2.0) and the environmental setting was described, with emphasis placed on any special environmental sensitivities (chapter 3.0). Program activities were then compared with the potentially affected environmental components to determine the environmental impacts of the proposed activities. To help define the affected environment and determine the significance of program-related effects, personal, written, and telephone contacts were made with applicable agencies.

Cumulative impacts result from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of who undertakes such actions. Cumulative impacts can result from individually minor, but collectively significant, actions taking place over a period of time. For this EIS, potential cumulative impacts are addressed for past, present, and future actions. Future actions were identified based on review of installation and regional land use plans and discussions with installation and regional planners.

Consistent with CEQ regulations, the scope of the analysis presented in this section was defined by the range of potential environmental impacts that could result. Resources that have a potential for impacts were considered in the analysis to provide the decision makers with sufficient evidence and analysis for evaluation of potential effects of the action. For this EIS, the environment is discussed in terms of 14 resource areas, which are discussed as applicable for each location.

Sections 4.1 through 4.11 provide discussions of the potential environmental consequences of the proposed GMD ETR program activities and the No Action Alternative. The amount of detail presented in each section is proportional to the potential for impacts. Sections 4.12 through 4.18 provide discussions of the following with regard to proposed program activities: conflicts with federal, state, and local land use plans, policies, and controls for the area concerned; energy requirements and conservation potential; natural or depletable resource requirements and conservation potential; adverse environmental effects that cannot be avoided; relationship between short-term use of the human environment and the maintenance and enhancement of long-term productivity; irreversible or irretrievable commitment of resources; Executive Order 13045, Federal Actions to Address Protection of Children from Environmental Health Risks and Safety Risks; and a summary of unresolved issues.
4.1 KODIAK LAUNCH COMPLEX

4.1.1 AIR QUALITY—KODIAK LAUNCH COMPLEX

This section addresses potential environmental impacts from changes in the air quality environment due to the proposed construction and operation of the GBI, target, IDT, and sensor elements of the GMD ETR at KLC, as well as the identification of potential cumulative impacts and mitigation measures. Impacts considered include potential effects from ongoing or planned activities at this site. Potential impacts were determined using the following criteria:

- Operations within attainment areas that could cause a detrimental change in attainment status of the area.
- Increases in ambient air pollutant concentration that could cause exceedances of the NAAQS or state AAQS.
- The U.S. Air Force standard for hydrogen chloride is 2 parts per million (ppm) for 60 minutes and 10 ppm for a maximum instantaneous level. These standards are based upon measured and estimated launch emission exposure concentrations and durations in the event of normal and catastrophic launches (National Research Council, Commission of Life Sciences, Board of Environmental Studies and Toxicology, Committee on Toxicology, Subcommittee on Rocket Emission Toxicants, 1998).
- The standard used for aluminum oxide is 150 micrograms per cubic meter (µg/m³) is based upon the maximum NAAQS level of PM-10 concentrations over a 24-hour period.
- Increases in air pollutant concentrations greater than 1 µg/m³ (averaged over 24 hours) from new or modified major stationary sources within 10 kilometers (6 miles) of a Class I area.

Appendix B includes a detailed description of these air quality standards.

4.1.1.1 No Action Alternative

Missile Defense Agency

Under the MDA’s No Action Alternative, launches of all types covered by the launch site operator’s license would continue to occur at KLC, although the GMD ETR would not be established and GBI and target launch scenarios would not be tested under more operationally realistic conditions. Missile propellant information for previous and predicted launches at KLC is shown in table 4.1.1-1.

The KLC EA predicted, under worst-case meteorological conditions, that NAAQS, Alaska AAQS, and U.S. Air Force and Non-criteria Pollutant guidance levels would not be exceeded during up to nine launches per year of the Athena-2, using Castor 120™ motors for propulsion (Federal Aviation Administration, 1996).

Operational emissions predicted at KLC include existing stationary sources. These stationary sources include three standby diesel generators operating at a maximum of 5 hours during launches, 1 hour per week for testing during non-launch periods and during commercial power outages (approximately 240 hours per year). Air quality impacts from these sources are considered to be temporary. (Federal Aviation Administration, 1996) Table 4.1.1-2 lists the estimated emissions generated by the four standby generators at KLC. KLC currently maintains a Pre-approved Limit Permit for these generators.

Upper Atmosphere

According to the KLC EA, potential contributions to the upper atmosphere include emissions from ground-level operations and exhaust emissions from launch vehicles. Up to nine launches per year of the Athena-2, using the Castor 120™ motors for propulsion, were determined by the KLC EA to have a small impact on the levels of ozone found in the stratosphere; however, the release of chlorine (from the chemical reaction from the release of hydrogen chloride) and alumina (from the chemical reaction from the release of aluminum oxide) into the stratosphere would make a minimal contribution to the overall impact of ozone depletion. (Federal Aviation Administration, 1996)
Federal Aviation Administration

Under the FAA’s No Action Alternative, the launch site operator license for KLC would not be renewed and no launches would be allowed to occur from KLC after September 2003. Therefore, no impacts to air quality would occur from launches at KLC.

4.1.1.2 Alternative 1

4.1.1.2.1 Ground-Based Interceptors

Construction

Construction at KLC, as described in section 2.3.1.1, would disturb approximately 14.4 hectares (35.5 acres). The majority of the ground disturbance would occur within 1 year, and it is projected that construction would take up to 15 months to complete. Construction emissions vary from day to day and activity to activity, with each activity having its own potential to release emissions. Because of the variability in timing and intensity of construction, estimating construction-phase pollutant emissions is difficult. Nevertheless, it is assumed that there would be PM-10 impacts from ground disturbance and other pollutants (carbon monoxide, oxides of nitrogen, volatile organic compounds, and oxides of sulfur) primarily emitted from construction equipment exhaust. Potential construction emissions were determined by using emission factors from various sources including the EPA. Conservative estimates are based on building square footage, acreage disturbed, and duration of construction, as well as general meteorological and soil information. For purposes of determining the level of fugitive dust generated, it was assumed all grading would be accomplished during the first year. Potential fugitive dust amounts were estimated using Air Quality Thresholds of Significance spreadsheets. Table 4.1.1-3 lists estimated carbon monoxide, oxides of nitrogen, volatile organic compounds, oxides of sulfur, and PM-10 emissions from construction equipment, earth moving and commuting workers anticipated during 15 months of construction of GBI facilities. Best Management Practices including proper tuning and preventative maintenance of construction vehicles would serve to minimize exhaust emissions and maximize vehicle performance.

<table>
<thead>
<tr>
<th>Emission</th>
<th>Year 1 (metric tons)</th>
<th>Year 2 (metric tons)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Carbon Monoxide</td>
<td>9.0 (10.5)</td>

<td>0.14 (0.15)</td>
</tr>
<tr>
<td>PM-10</td>
<td>34 (37.5)</td>
<td>-</td>
</tr>
</tbody>
</table>

Approximately 68 metric tons (75 tons) of PM-10 could be produced during the construction of the facilities. Best Management Practices would be used to reduced PM-10 emissions by half to approximately 34 metric tons (37.5 tons) using dust suppression measures such as periodically watering the areas being graded, minimizing unnecessary traffic, reducing vehicle speeds near
the work areas, and wet sweeping or otherwise removing soil and mud deposits from paved roadways and parking areas.

For conservative analytical purposes, it is assumed that 50 of the 100 additional construction personnel would utilize an existing mancamp located approximately 4 kilometers (3 miles) from the construction site. The remaining 50 were assumed to commute to and from the City of Kodiak or to and from accommodations in the area surrounding KLC. Commuting emission levels were based upon federal primary exhaust emission standards for vehicles for an entire day of commuting (to KLC and back). If either the additional mancamp was constructed or the existing mancamp was added to, then all 100 construction personnel would be housed in close proximity to KLC, greatly reducing the potential commuting emissions.

Construction emission levels are below \textit{de minimis} levels set by the federal government for non-attainment areas. The \textit{de minimis} thresholds are federal limits listed in 40 CFR 51.583(b)(1). Federal actions with emissions below the \textit{de minimis} levels are presumed to conform, that is, not cause or contribute to new violations of NAAQS, in areas that are in non-attainment. For the least severe nonattainment areas, the \textit{de minimis} level for each criteria pollutant (and their precursors, in the case of ozone) is 90.7 metric tons (100 tons) per year.

Construction would be conducted in accordance with applicable federal and state regulations and permits. While the construction would cause an increase in air pollutants, the impact would be both temporary and localized. Once construction ceased, air quality would return to its former level. Since the area is currently in attainment for all federal standards and construction emissions would be within \textit{de minimis} levels for non-attainment areas, it is anticipated that the proposed construction would not cause exceedances of the NAAQS or Alaska AAQS and would not have a long-term impact to air quality in the area.

\textbf{Operation}

\textit{Pre-Launch Activities}

The manufacturing of GBI vehicle components would occur offsite in existing facilities that normally perform this type of production, and emissions at these locations have not been included in the scope of this EIS. The components would arrive complete, requiring only final onsite safety and quality checks before assembly.

Pre-launch activities would include the transportation of the interceptor missile boosters, payloads, and support equipment by either air or ship. This transportation would result in some mobile exhaust emission, but these emissions would be intermittent and would not have a measurable impact on regional air quality. The interceptor could arrive at KLC with the EKV attached, or the booster may be shipped separately from the EKV. Either way, integration and assembly operations would be performed at KLC.

Onsite fueling of the interceptor or EKV would not be required; the interceptor motor would utilize pre-loaded solid propellants. Each EKV would contain pre-loaded liquid propellant and oxidizer. The propellants would be delivered to the launch site in pre-filled and sealed tanks that would be ready to be installed onto the vehicle. Installation would only require mechanical tubing connections.
During nominal propellant tank installation, the propellants remain sealed inside their tanks. The likelihood of an accidental release of the liquid fuel or oxidizer would be low. However, if such an accident were to occur, it would most likely occur during missile assembly. Table 4.1.1-4 indicates the results of analysis using the U.S. Air Force Toxic Corridor Model computer model to determine distances at which the Immediately Dangerous to Life and Health (IDLH) health standard could be exceeded assuming all 7.5 liters (2 gallons) of fuel and 5.5 liters (1.5 gallons) of oxidizer were released to the atmosphere during an accident. The IDLH is the level of exposure (not time-weighted) above which it is thought a person would suffer life-threatening or irreversible health effects or other injuries that would impair them from escaping the hazardous environment. The IDLH level was the only level of concern as others are based on time weighted averages over prolonged exposures.

Source: Center for Disease Control and Prevention, 2002a, b; Asia Pacific Space Launch Centre EIS Site, 2002.

a The National Institute for Occupational Safety and Health (NIOSH) Immediately Dangerous to Life and Health (IDLH) is the level of exposure (not time-weighted) above which it is anticipated a person would suffer life-threatening or irreversible health effects or other injuries that would impair them from escaping the hazardous environment.

b Exceedance Distance—Average of U.S. Air Force Toxic Corridor model results for 15-minute and 30-minute averaging time and multiple stability classes.

ppm = parts per million by volume.
mg/m³ = milligrams per cubic meter.

Actual hazard distances would depend on the propellant released, the amount released, meteorological conditions, and emergency response measures taken. AADC's approved SOPs would be implemented and would include personal protection equipment procedures. Establishment of and adherence to these SOPs would minimize the potential hazards to personnel in the unlikely event of an unplanned propellant release. The low likelihood of such an event and the implementation of approved emergency response plans would limit the impact of such a release.

Personnel would include a combination of contractor, military, and government civilian. The largest manpower buildup at KLC would be 55 the first month, 120 the second month, and 235 the third month to support a dual interceptor launch. It is assumed that approximately 50 personnel would be housed at the existing mancamp on Kodiak Ranch. If the additional mancamp is not constructed on KLC or the existing mancamp is not added on to, then it is conservatively estimated that the remaining 185 personnel would commute daily to KLC from accommodations in the surrounding areas and within the City of Kodiak during a peak month. Commuting emission levels were based upon federal primary exhaust emission standards for vehicles for an entire day of commuting (to and from KLC) and estimated to be 2.0 metric tons (2.2 tons) of carbon monoxide and 0.24 metric tons (0.26 tons) of oxides of nitrogen.
Offsite power sources are planned for primary use, with emergency generators supplying backup power. The emergency backup generators would be operated under appropriate permits and restrictions. In addition to the generators themselves, appropriate ASTs would be installed adjacent to each generator. Table 4.1.1-5 lists the generator and AST sizes for each facility. Table 4.1.1-6 lists the possible emissions associated with each generator.

The generators would operate as backup during launches, weekly for testing during non-launch periods, and during commercial outages. The total operating time is estimated at a maximum of 250 hours per year. Use of these generators would require an amendment to the existing Pre-approved Limit Permit.
Table 4.1.1-6 also shows the total emissions from GBI, target, IDT, sensors, and TPS-X at KLC. Although not in a non-attainment area, these totals are below the de minimis thresholds and therefore would not cause exceedances of the NAAQS or Alaska AAQS.

Launch Activities

Alternative 1 includes up to a total of five missile launches (GBI and target combined) per year at KLC over the duration of the test program. Table 4.1.1-7 lists propellant information for the proposed GBI. Table 4.1.1-8 lists possible emissions from stage one of the proposed single GBI launch.

Source: Nyman, 2003

Dual GBI launches were analyzed using Open Burn/Open Detonation Dispersion Model (OBODM) to determine exhaust emissions of aluminum oxide, hydrogen chloride, and carbon monoxide. Table 4.1.1-9 lists emission concentrations and standards. As shown on table 4.1.1-9, concentrations produced by dual launches of a dual GBI would remain within NAAQS, Alaska AAQS, and U.S. Air Force standards. It is anticipated that a nominal single launch would also remain within NAAQS and U.S. Air Force standards as fewer emissions would be released during a single launch.

While the area KLC is located in is in attainment for all federal emission standards, federal de minimis threshold limits listed in 40 CFR were used to compare oxides of nitrogen and carbon monoxide. In the event that five GBIs were launched in a year, the conservatively estimated annual emissions for oxides of nitrogen were determined to be 28.8 metric tons (31.8 tons), below the 45.4-metric-ton (50-ton) standard. Carbon monoxide was calculated at 4.9 metric tons (5.4 tons) for five launches, which is well below the 90.7-metric-ton (100-ton) annual standard.

(1) Based upon NAAQS
(2) Based upon the maximum NAAQS level of PM-10 concentrations over a 24-hour period
(3) Based upon Air Force standards that measured and estimated launch emission exposure concentrations and durations in the event of normal and catastrophic launches

Personnel would be evacuated to a safe distance before a launch according to established launch procedures as stated in section 3.1.7, Health and Safety. Due to the mobile nature of the interceptor itself, only a small portion of the launch exhaust would be emitted near the ground. With typical meteorological conditions, prevailing winds from the northwest, the ground-cloud of exhaust would be carried to the ocean. In all cases of weather conditions, significant air quality impacts due to missile launches are not anticipated.

If flight termination becomes necessary, the potential resulting fire would cause short-term impacts to air quality in the form of combustion byproducts and potentially hazardous fumes. Most or all of the solid propellant fuel would likely burn up before being extinguished. These combustion byproducts would be similar to those previously described for a nominal launch.

Modeling using the OBODM was also performed to analyze emissions produced in the highly unlikely occurrence of an on-pad accident involving dual GBIs. The modeling showed that both the 1-hour and peak hydrogen chloride Air Force standards would be exceeded (table 4.1.1-9). The 8-hour, 24-hour, and IDLH hydrogen chloride standards were not exceeded. All other standards would continue to be within NAAQS and Alaska AAQS. The consequences to regional air quality would be localized for both the 1-hour and peak hydrogen chloride Air Force standard (exceedance out to 1 kilometer [0.6 mile] and 3.7 kilometers [2.3 miles], respectively beyond the KLC boundary) and would be of a short duration. The modeling included both day and nighttime meteorological data. The nighttime data is generally very calm wind conditions which results in higher emission concentrations. Due to the highly unlikely potential for a dual accident, the localized short term nature of the air quality exceedence, and the conservative nature of the modeling data inputs, the impact to regional air quality is considered minor.

**Post-Launch Activities**

Post-launch activities would include the removal of all mobile equipment and assets brought to KLC. A negligible impact would be anticipated to air quality resulting from slightly increased vehicular emissions and localized amounts of fugitive dust (PM-10).
4.1.1.2.2 Targets

Construction

Approximately 10.5 hectares (26 acres) of land would be disturbed during the construction of target facilities. Calculation of construction emissions followed the same methodology as described in section 4.1.1.2.1. Table 4.1.1-10 lists estimated carbon monoxide, oxides of nitrogen, volatile organic compounds, and oxides of sulfur emissions anticipated during up to 15 months of construction of target missile facilities. Best Management Practices, including proper tuning and preventive maintenance of construction vehicles, would serve to minimize exhaust emissions and maximize vehicle performance.

Table 4.1.1-10: Potential Construction Emissions for Target Facilities at KLC

</tr>
<tr>
<td>PM-10</td>
<td>25 (27.5)</td>
<td></td>
</tr>
</tbody>
</table>

Approximately 50 metric tons (55 tons) of PM-10 could be produced during the construction of the facilities. The use of Best Management Practices would reduce this number by half to approximately 25 metric tons (27.5 tons) using dust suppression measures such as periodically watering the areas being graded, minimizing unnecessary traffic, reducing vehicle speeds near the work areas, and wet sweeping or otherwise removing soil and mud deposits from paved roadways and parking areas. Impacts due to personnel at KLC for construction of target facilities would be the same as those described in section 4.1.1.2.1 for construction of GBI facilities.

Operation

Pre-Launch Activities

Pre-launch activities include the transportation of the target to KLC and assembly of the target at KLC. The mobile exhaust emissions resulting from transportation of the target would be intermittent and would not have a measurable impact to regional air quality. The targets would be assembled and stored in the Missile Assembly Building until launch.

If used as a target, the fourth stage of a Peacekeeper target would utilize a single liquid propellant (hydrazine), and onsite fueling would be required. Although total vapor emissions can vary depending on the propellant transfer equipment used and how it is assembled, it is anticipated that only very small amounts (approximately 10 grams [0.4 ounce]) of vapors would be released to the atmosphere during the transfer operation. These normal fueling operations would marginally impact air quality for momentary periods of time.

It is unlikely that a propellant release larger than that described above would occur at KLC. However, if such an accidental release were to occur, it would most likely occur during fueling. A reasonable scenario would involve failure of the transfer equipment or valves. The analysis
assumes a leak contained over a 3-minute period that releases up to 17 liters (4.5 gallons) of hydrazine fuel. Analysis indicated no potential exceedances of the IDLH health standard of 50 ppm. The low likelihood of such an occurrence and the implementation of approved emergency response plans would limit the impact of such a release.

Emergency generators would supply backup power to target facilities with offsite commercial power sources. The emergency backup generators would be operated under appropriate permits and restrictions. In addition to the generators themselves, appropriate ASTs would be installed adjacent to each generator. Table 4.1.1-11 lists the generators and the size of ASTs for each facility.

</tbody>
</table>

The generators would operate as backup during launches, weekly for testing during non-launch periods, and during commercial outages. The total time of operation is estimated at a maximum of 250 hours per year. Emissions produced during the generators’ expected limited operation are listed in table 4.1.1-6. Use of these generators would require an amendment to the existing Pre-approved Limit Permit. These levels of emissions would not be expected to impact regional air quality.

**Launch Activities**

Proposed target launches would be similar to previous target launches at KLC. These land launched target missiles could consist of one of several types of missiles including Strategic Target System, Minuteman II Target, Peacekeeper Target, and Trident I (C4) Target. Table 4.1.1-12 lists missile propellant information, and table 4.1.1-13 lists potential emission constituents during Stage I for each proposed missile. A total of five missile launches (GBI and/or target) per year would be anticipated at KLC over the duration of the program.

Each launch is a discrete event. The logistics of the launch would allow sufficient time between launches so that no exhaust from one launch would impact the ambient air quality of another launch. The conclusion presented in the KLC EA was that overall impacts to regional air quality are not expected to be adverse and would remain within NAAQS and state AAQS for a single launch of the Athena 2 missile with the Castor 120™ motor. (Federal Aviation Administration, 1996) The nominal launch of a single Peacekeeper Target is anticipated to remain within NAAQS, Alaska AAQS, and Air Force standards as, the first stage of a Peacekeeper Target is a military version of the Castor 120 motor used in the Athena 2 missile.
Dual Peacekeeper Target launches were analyzed using OBODM to determine exhaust emissions of aluminum oxide, hydrogen chloride, and carbon monoxide. Dual emissions were modeled using the Peacekeeper Target as it is the largest of the proposed target vehicles. Emission concentrations and standards are listed in table 4.1.1-14. As shown in table 4.1.1-14, the level of hydrogen chloride would be below the 1-hour Air Force standard, but would exceed the peak hydrogen chloride standard for a short duration (out to a distance of 400 meters (1312 feet) beyond the KLC boundary). The 8-hour, 24-hour, and IDLH hydrogen chloride standards were not exceeded. Other emissions are shown to be within NAAQS standards.

(1) Based upon NAAQS  
(2) Based upon the maximum NAAQS level of PM-10 concentrations over a 24-hour period  
(3) Based upon Air Force standards that measured and estimated launch emission exposure concentrations and durations in the event of normal and catastrophic launches

KLC is considered to be in attainment for all federal emission standards; however, federal de minimis threshold limits listed in 40 CFR were used to compare levels of carbon monoxide and oxides of nitrogen. In the event that five Peacekeeper Target launches occur in a year, the conservative calculation of annual emissions of carbon monoxide would be 48.8 metric tons (53.8 tons), which is below the 90.7-metric-ton (100-ton) annual standard. Emissions of oxides of nitrogen were estimated to be 18.3 metric tons (20.2 tons), also below the de minimis standard of 45.3 metric tons (50 tons).

Personnel would be evacuated to a safe distance before a launch according to established launch procedures as stated in section 3.1.7, Health and Safety. Due to the mobile nature of the target missiles, only a small portion of the launch exhaust would be emitted near the ground. With typical meteorological conditions, prevailing winds from the northwest, the ground-cloud of exhaust would be carried to the ocean. In all cases of weather conditions, significant air quality impacts due to missile launches are not anticipated.

If flight termination becomes necessary, the potential resulting fire would cause short-term impacts to air quality in the form of combustion byproducts and potentially hazardous fumes. Most or all of the solid propellant fuel would likely burn up before being extinguished. These combustion byproducts would be similar to those previously described for a nominal launch.

Modeling using the OBODM was also performed to analyze emissions produced in the highly unlikely occurrence of on-pad accidents involving dual Peacekeeper Targets. The model results show that both the 1-hour and peak hydrogen chloride Air Force standards would be exceeded (table 4.1.1-14). The 8-hour, 24-hour, and IDLH hydrogen chloride standards were not exceeded. All other standards would continue to be within NAAQS and Alaska AAQS. The consequences to regional air quality would be localized for both the 1-hour and peak hydrogen chloride Air Force standard (exceedance out to 6.5 kilometers [4 miles] and 7 kilometers [4.3 miles], respectively beyond the KLC boundary) and would be of a short duration. Due to the highly unlikely potential for a dual accident, the localized short term nature of the air quality exceedence, and the conservative nature of the modeling data inputs, the impact to regional air quality is considered minor.
Post-Launch Activities

Post launch activities would include the removal of all mobile assets brought to KLC. This removal could result in small localized amounts of PM-10, which would have only minor impacts to air quality.

4.1.1.2.3 In-Flight Interceptor Communication System Data Terminal

Construction

Alternative 1 would require the construction of one IDT (among three alternative sites), one COMSATCOM (among four alternatives), and connecting roads. The greatest emissions would be during site preparation activities that include grubbing and clearing of vegetation, site grading and stockpiling of soil and select fill materials. The largest of the IDT sites would require approximately 5.9 hectares (14.6 acres) of land to be disturbed, and one COMSATCOM site would disturb 2.8 hectares (7.0 acres). Potential construction emissions for both the largest IDT site and one COMSATCOM are listed in table 4.1.1-15.

<table>
<thead>
<tr>
<th>Emission</th>
<th>Year 1 metric tons (tons)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Carbon Monoxide</td>
<td>0.72 (0.79)</td>
</tr>
<tr>
<td>Oxides of Nitrogen</td>
<td>3.30 (3.60)</td>
</tr>
<tr>
<td>Volatile Organic Compounds</td>
<td>0.51 (0.57)</td>
</tr>
<tr>
<td>Oxides of Sulfur</td>
<td>0.23 (0.25)</td>
</tr>
<tr>
<td>PM-10</td>
<td>20.5 (23.0)</td>
</tr>
</tbody>
</table>

Construction activities for IDT and COMSATCOM facilities could produce approximately 41 metric tons (46 tons) of PM-10. It is anticipated that this PM-10 volume would be reduced by half to 20.5 metric tons (23 tons) through implementation of Best Management Practices for dust suppression during site preparation activities. Only minor impacts would be anticipated to air quality from construction activities. Site preparation activities would be relatively short in duration affect a relatively small footprint, and would employ a variety of Best Management Practices.

Operation

Operation of the IDT and COMSATCOMs would have little effect on regional air quality. Power would be provided by offsite commercial power sources, however in the event of loss of power a 275 kW diesel generator would be utilized along with the 3,785-liter (1,000-gallon) AST for fuel. Emissions produced during the generator’s limited operation are listed in table 4.1.1-6. These levels of emissions would not be expected to impact regional air quality. The generator would be tested weekly during non-launch periods and during power outages, approximately 250 hours a year. Use of this generator would require an amendment to the existing Pre-approved Limit Permit.
Personnel associated with the IDT and COMSATCOMs would be included in the up to 235 personnel needed to support a dual interceptor launch and would not cause an additional air quality impact.

### 4.1.1.2.4 Sensors

#### Construction

Alternative 1 would utilize an existing gravel pad area for mobile telemetry and would not require new construction; therefore there would be no air quality impacts.

#### Operation

Operation of the mobile telemetry would have a minor impact on the regional air quality. Power would be provided by two 10-kW generators for the mobile telemetry. Anticipated emissions from the use of these generators would be for a 1-week period, up to five times per year. Table 4.1.1-6 lists the possible emissions from use of the generators. Use of these generators would require an amendment to the existing Pre-approved Limit Permit.

### 4.1.1.2.5 TPS-X

#### Construction

The installation of the TPS-X at KLC would require the construction of a pad for the 38- by 58-meter (125- by 190-foot) hardstand and disturbance of approximately 0.3 hectare (0.8 acre). The potential TPS-X location would be the same as for the potential IDT site south of the Loran-C Station. Table 4.1.1-16 lists estimated emission levels of carbon monoxide, oxides of nitrogen, volatile organic compounds, oxides of sulfur and PM-10.

#### Table 4.1.1-16: Potential TPS-X Construction Related Emissions at KLC

<table>
<thead>
<tr>

<td>0.77 (0.85)</td>
</tr>
</tbody>
</table>

It is anticipated that the volume of PM-10 produced during construction would be reduced by half through the implementation of Best Management Practices for dust suppression during site preparation activities.

#### Operation

The prime power unit for the TPS-X at KLC would be a 1.5-MW generator that would provide power to the radar during testing. The generator is assumed to be in operation for 3 weeks (24 hours a day, 7 days a week) five times a year during launch activities. The total time of operation is estimated at a maximum of 2,520 hours per year. Potential generator emissions for
the TPS-X are listed in table 4.1.1-6. Use of this generator would require an amendment to the existing Pre-approved Limit Permit.

4.1.1.3 Alternative 2

4.1.1.3.1 Targets

Target activities associated with Alternative 2 would be similar to those of Alternative 1.

Construction

Construction would include a total disturbed area of 10.5 hectares (26 acres), the same as identified for Alternative 1. Construction impacts would be as described for Alternative 1.

Operation

Operation impacts from pre-launch, launch, and post-launch activities of target launches in Alternative 2 would be similar to those described for target launches in Alternative 1 in section 4.1.1.2.2.

4.1.1.3.2 Sensors

Effects from construction and operation of a mobile telemetry at KLC for Alternative 2 would be the same as described for the sensors of Alternative 1 in section 4.1.1.2.4.

4.1.1.4 Alternative 3

Alternative 3 would include all aspects of Alternative 1. Because Alternative 1 includes GBIs, targets, and all associated facilities, the construction and launch impacts for Alternative 3 would be as described for Alternative 1.

4.1.1.5 Cumulative Impacts

Due to the limited industrialization of Kodiak Island and the surrounding environment, the potential cumulative impacts to air quality due to the proposed interceptor and target facility construction and launches would not be substantial. No other construction is anticipated to occur at the same time as the proposed construction activities. The KLC EA indicated no significant impacts to air quality as a result of nine annual launches and that impacts do not accumulate with multiple launches (Federal Aviation Administration, 1996). It is not likely that the Proposed Action of up to five launches (GBI and/or target) in conjunction with other currently planned or anticipated launches at KLC would exceed nine launches per year, the level of activity analyzed in the KLC EA.

Dual launches of either interceptors or targets would result in increased exhaust emissions compared to a single launch. However, the emissions would disperse quickly and the overall air quality would continue to remain within NAAQS and Alaska AAQS. Proposed activities along with current activities at KLC, including the use of three standby generators, are not anticipated to result in cumulative impacts to air quality.
4.1.1.6 Mitigation Measures

No air quality mitigation measures are proposed for the GMD ETR activities at KLC.

4.1.2 AIRSPACE—KODIAK LAUNCH COMPLEX

Site preparation activities for interceptor, target missiles, IDT, or the TPS-X would have no impact on controlled or uncontrolled airspace, special use airspace, en route airways and jet routes, or airfields and airports in the ROI. Since site preparation activities would not restrict a clear view of runways, helipads, taxiways, or traffic patterns from the airport air traffic control tower, decrease airport capacity or efficiency, affect future VFR or IFR, or affect the usable length of an existing or planned runway, they would also not constitute an obstruction to air navigation.

Potential impacts from flight test activities are discussed below for each alternative.

4.1.2.1 No Action Alternative

Missile Defense Agency

Under the MDA’s No Action Alternative, launches would continue to occur at KLC although the GMD ETR would not be established and GBI and target launch scenarios would not be tested under more operationally realistic conditions. The use of KLC for flight preparation and launches has been analyzed in the North Pacific Targets Program EA (U.S. Army Space and Missile Defense Command, 2001b), the KLC EA (Federal Aviation Administration, 1996) and two U.S. Air Force documents (U.S. Department of the Air Force, 1997a; 2001). These documents concluded that close coordination with the FAA would result in no adverse effects to airspace from launches at KLC.

Under the MDA’s No Action Alternative, KLC would continue to conduct up to nine launches per year through September 2003 as specified in the current launch site operator license. The current license is scheduled for renewal in September 2003. The new license, if issued would outline the terms under which launches would be conducted at KLC. The renewal period would be for another 5 years.

Federal Aviation Administration

Under the FAA’s No Action Alternative, the launch site operator license for KLC would not be renewed and no launches would be allowed to occur from KLC after September 2003. Therefore, there would be no impacts to airspace from launches at KLC.

4.1.2.2 Alternative 1

Potential airspace impacts from implementation of the Proposed Action include the following activities:

- Potential impacts to controlled and uncontrolled airspace
- Potential impacts to existing special use airspace
- Potential impacts to en route airways and jet routes
- Potential impacts to airports and airfields
Controlled and Uncontrolled Airspace

The ROI, located in international uncontrolled class G airspace, has no formal airspace restrictions governing it. Before launching the GBI or target missile from KLC, NOTAMs would be sent in accordance with FAA protocols and DoD requirements. The U.S. NOTAM System, Sections 3-2n(1)(a) and (b), deals with operations/exercises over the high seas, host nation territory, international airspace, and bare-base locations, and specifies the International NOTAM office coordination requirements and procedures as per U.S. Army Regulation 95-10, *Department of Defense Notice to Airmen (NOTAM) System*, 1 January 1997.

To satisfy airspace safety requirements in accordance with DoD requirements, the KLC Range Safety Officer would obtain approval from the Administrator, FAA. Provision would be made for surveillance of the affected airspace. In addition, safety regulations dictate that launch operations would be suspended when it is known or suspected that any unauthorized aircraft have entered any part of the surface danger zone until the unauthorized entrant has been removed or a thorough check of the suspected area has been performed. When the probability is less than $1 \times 10^{-7}$ that an aircraft would be in an unsafe proximity to the GBI or target missile, the Range Safety Office may establish segmented safety zones to allow for some unrestricted air routes under the flight path during the launch window.

If the TPS-X radar is located at KLC, EMR hazard zones would be established. The potential interference distances are shown in figure 2.3.1-8. The personnel exclusion area would extend for 150 meters (492 feet) in front of the radar. The FAA would be requested to establish a navigation warning advising aircraft to remain at least 1,500 meters (4,900 feet) from the TPS-X radar site during use. EEDs in the presence and shipping phase, such as a missile mounted on an aircraft, would need to be at least 800 meters (2,625 feet) from the radar. EEDs on the ground in the handling phase would need to be at least 400 meters (1,312 feet) from the radar due to potential sidelobe exposure. The interference areas are directional, and would be centered on the launch azimuth, between 135 degrees and 225 degrees.

A visual survey of the area would be conducted to verify that all personnel are outside the hazard zone before startup. Personnel may not enter these hazard zones while the radar is in operation. The radar is prevented from illuminating in a designated cutoff zone, in which operators and all other system elements would be located. Potential safety consequences associated with radar interference with other electronic and emitter units (flight navigation systems, tracking radars, etc.) would also be examined before startup. Adherence to AADC, FAA, and DoD safety procedures relative to radar operations would preclude significant impact to airspace.

Special Use Airspace

There is no special use airspace in the KLC ROI, and as such there would be no impact on airspace from proposed program activities.

En Route Airways and Jet Routes

Coordination between KLC and the controlling airspace agencies (Anchorage and Oakland ARTCC) would minimize potential impacts to the commercial air corridors entering and exiting Kodiak Airport north of KLC (figure 3.1.2-1), and the flexible tracks south of KLC that are used to transition to the North Pacific route system.
Airports and Airfields
The proposed activities in Alternative 1 would not restrict access to, nor affect the use of, existing airfields and airports in the ROI.

4.1.2.3 Alternative 2
The proposed activities at KLC under Alternative 2 would be similar to those described under Alternative 1. Alternative 2 involves launching only target missiles, but the potential impacts to airspace would be the same.

4.1.2.4 Alternative 3
Alternative 3 would include all aspects of Alternatives 1 and 2. Because Alternative 1 includes GBIs, targets, and all associated facilities, the construction and flight impacts for Alternative 3 would be as described for Alternative 1.

4.1.2.5 Cumulative Impacts
There is no airspace segregation method such as a warning or restricted area to ensure that international airspace would be cleared of nonparticipating aircraft. However, missile launches are short-term, discrete events. The KLC EA concluded there would be no cumulative impact to airspace for nine annual launches (Federal Aviation Administration, 1996). It is not likely that the Proposed Action of up to five launches (GBI and/or target) in conjunction with other currently planned or anticipated launches at KLC would exceed nine launches per year, the level of activity analyzed in the KLC EA. The use of the required scheduling and coordination process for international airspace and adherence to applicable DoD directives and U.S. Army regulations concerning issuance of NOTAMs and selection of missile firing areas and trajectories further reduce the potential for incremental, additive, cumulative impacts.

4.1.2.6 Mitigation Measures
The required coordination procedures with the FAA and scheduling requirements of KLC minimize any potential impacts so that no mitigation measures have been identified as necessary for the GMD ETR proposed activities. NOTAMs would be sent in accordance with FAA protocols and DoD requirements.

4.1.3 BIOLOGICAL RESOURCES—KODIAK LAUNCH COMPLEX
The biological resources analytical approach involved evaluating the potential impacts of the Proposed Action and alternatives, such as construction, site preparation activities, use of existing and new sensors, and missile launches, on vegetation, wildlife, threatened and endangered species, and sensitive habitat within the ROI. Impacts that could result from construction and other site preparation activities include disturbance and removal of vegetation and disturbance to wildlife from the accompanying noise and presence of personnel. Impacts could also result from launch-related activities such as noise, air emissions, debris impacts, and the use of radar equipment.
Criteria for assessing potential impacts to biological resources are based on (1) the number or amount of the resource that would be impacted relative to its occurrence at the project site, (2) the sensitivity of the resource to proposed activities, and (3) the duration of the impact. Impacts are considered substantial if they have the potential to result in reduction of the population size of federally listed threatened or endangered species, degradation of biologically important unique habitats, substantial long-term loss of vegetation, or reduction in capacity of a habitat to support wildlife.

All transportation of equipment and materials such as fuels would be conducted in accordance with applicable federal (DOT) and state regulations. Hazardous materials would be inspected prior to accepting a shipment. Bulk hazardous materials drums would be stored in approved containers during transportation that meet National Fire Protection Association industrial fire protection codes and required containment systems. Spill response materials such as sorbents, drain covers, mops, brooms, drum repair materials and tools, warning signs and tapes, and personal protective equipment would be readily available for use in the event of an unplanned release of hazardous materials. These SOPs for spill prevention, containment, and control measures while transporting equipment and materials would preclude impacts to biological resources.

GMD ETR program personnel would remove all mobile equipment/assets brought to the installation at the conclusion of its testing activities. Transportation for removal of equipment would be the same as when it was brought into the installation. These activities would result in impacts similar to, but less than, those caused by site preparation. All mobile assets would be located on existing gravel pads at KLC.

4.1.3.1 No Action Alternative

Missile Defense Agency

Under the MDA’s No Action Alternative, launches would continue to occur at KLC, although the GMD ETR would not be established and GBI and target launch scenarios would not be tested under more operationally realistic conditions. KLC would continue to provide ongoing support to single Strategic Target System launches from the GMD Element; however, test scenarios would be severely limited. The KLC EA (Federal Aviation Administration, 1996) indicated no significant impact to biological resources from nine annual missile launches. The North Pacific Targets Program EA (U.S. Army Space and Missile Defense Command, 2001b) determined that no significant impacts would occur to biological resources as a result of launching a Strategic Target System Missile. The Strategic Target System launches would continue to be managed within the nine launches previously analyzed in the KLC EA (Federal Aviation Administration, 1996) and no additional impacts to biological resources would be expected to occur.

Federal Aviation Administration

Under the FAA’s No Action Alternative, the launch site operator license for KLC would not be renewed, and no launches would be allowed to occur from KLC after September 2003. Therefore, there would be no impacts to biological resources from launches at KLC.
4.1.3.2 Alternative 1

4.1.3.2.1 Ground-Based Interceptors

Construction

Vegetation
The proposed activities under Alternative 1 would require construction as described in section 2.3.1.1. No significant impacts to vegetation are anticipated, since new construction would occur mainly in upland areas of hairgrass-mixed forb meadow, one of the predominant vegetation types at KLC. This loss of vegetation (approximately 14 hectares [36 acres]) would represent only a small portion of the total vegetation available within KLC boundaries and the adjacent region.

Threatened and Endangered Plant Species. No federally proposed or listed candidate, threatened, or endangered plant species have been observed within the boundaries of KLC. Therefore, there would be no impacts to listed plant species.

Wildlife
Impacts from ground disturbance and equipment noise could include loss of habitat, displacement of wildlife, increased stress to wildlife, and disruption of daily or seasonal behavior. As stated above, new construction would occur mainly in upland areas of hairgrass-mixed forb meadow, one of the predominant vegetation types at KLC. Additional habitat for those species that could potentially be displaced is located adjacent to those areas proposed for disturbance. Site preparation activities would not result in impacts to Essential Fish Habitat since no water bodies would be affected.

Noise rather than the sight of machines appears to cause more disturbance to wildlife. The effects of noise on wildlife vary from serious to no effect in different species and situations. Behavioral responses to noise also vary from startling to retreat from favorable habitat, due partly to the fact that wildlife can be very sensitive to sounds in some situations and very insensitive to the same sounds in other situations (Larkin, 1996). Since there are no absolute standards of short-term noise impacts for potentially noise-sensitive species, a short-term maximum noise exposure of 92 dB was suggested as a significant cut-off for impacts in a noise monitoring study for the HEDI I missile (U.S. Army Strategic Defense Command, 1989b; 1990). This noise level is equivalent to being 1 meter (3 feet) from a power lawnmower. This noise level is similar to the range of 80 to 90 dBA defined as known to disturb waterfowl and wildlife in the KLC EA (Federal Aviation Administration, 1996).

Typical noise levels at 15 meters (50 feet) from construction equipment range from 70 to 98 dBA. Wildlife is known to exhibit a startle response when exposed to short-term noise impacts. The combination of increased noise levels and human activity would likely displace some small mammals and birds that forage, feed, nest, or have dens within this 15-meter (50-foot) radius. However, sufficient foraging and feeding habitat occurs in adjacent areas. Studies (U.S. Department of the Air Force, 1997) indicate that birds usually show signs of disturbance, such as fluttering of wings, when a noise event occurs, but quickly return to normal behavior after the event. Although construction activities could cause flushing (birds suddenly flying up), this is a common reaction to sudden natural sounds that only slightly increases the energy expenditure of individual birds. Some wildlife may leave the area permanently, while others may likely
become accustomed to the increased noise and human presence. Construction is therefore not expected to have a long-term significant adverse effect on wildlife.

**Threatened and Endangered Wildlife Species.** Disturbance from site preparation activities would be restricted mainly to areas within 15 meters (50 feet) from the construction site. The closest federally endangered Steller sea lion haulout area, approximately 5 kilometers (3 miles) away on Ugak Island, would not be affected by site preparation noise. Federally threatened Steller’s eiders and endangered short-tailed albatross offshore would also be outside the range of the highest site preparation noise levels and are not anticipated to be affected.

**Environmentally Sensitive Habitat**

Wetlands can be impacted both directly and indirectly. Direct impacts can result from filling, dredging, or flooding. Indirect impacts can be caused by disturbance to adjacent land that results in degradation of water quality from chemical or sedimentary runoff. Given the lack of practicable alternative sites in combination with the measures taken to minimize wetland impacts, compliance with Executive Order 11990, *Protection of Wetlands*; DOT Order 5660.1A, *Order on Preservation of the Nation’s Wetlands*; and FAA Order 1050.1D, *Policies and Procedures for Considering Environmental Impacts* has been demonstrated.

Most new construction required for the Proposed Action would be located in upland areas. Construction of the GBI launch silos or launch pad and perimeter fencing around the launch area could disturb approximately 0.6 hectare (1.6 acres) of palustrine, emergent, persistent, seasonally flooded wetlands and 0.2 hectare (0.4 acre) of palustrine, scrub/shrub, broad-leaved deciduous, saturated wetlands (figure 4.1.3-1). The fence line layout is preliminary and could likely be altered before construction to avoid the wetlands. Indirect disturbance to wetlands would be minimized by implementing appropriate techniques to control runoff and other Best Management Practices discussed below.

The following examples of Best Management Practices for soil erosion control that AADC applies during construction activities would further minimize impacts to wetlands:

- Site preparation—vegetation preservation and protection, topsoil preservation, dust control, and temporary gravel construction entrance and exit
- Surface stabilization—temporary and permanent seeding and use of mulches and fabric and gravel blankets
- Runoff control and conveyance measures—installation of diversions, dikes, grassed waterways, and temporary slope drains
- Sediment barriers—straw bale and rock barriers, sediment fences
- Sediment traps and basins
- Stream protection—temporary stream crossings and streambank stabilization
- Protection of soil and fill storage piles

(Federal Aviation Administration, 1996)
EXPLANATION

1. Closed Sitka Spruce Forest
2. Open Sitka Spruce Forest
3. Closed Alder Shrubland
4. Closed Mixed Alder/Willow Shrubland
5. Low Shrub-Forb Meadow
6. Open Willow-Hairgrass-Mixed Forb Meadow
7. Mixed Dwarf Shrub-Graminoid Meadow
8. Hairgrass-Mixed Forb Meadow
9. Lupine Meadow
10. Disturbed
11. Permanently flooded bodies of water
12. Permanently flooded waterbodies with rooted vascular aquatic vegetation
13. Semipermanently flooded areas, less than 30 percent cover of vegetation
14. Saturated, emergent sedge-forb or sedge-forb-moss meadows
15. Semipermanently flooded emergent sedge marshes
16. Saturated, tall shrub thickets and graminoid-dwarf shrub-moss
17. Saturated, shrub meadows and shrub bogs with semipermanently flooded, emergent sedge
18. Saturated sedge moss
19. Subtidal, low energy, brackish bodies of open water
20. Brackish marsh and beach vegetation flooded irregularly by tidal water
21. Unvegetated beaches
22. Unvegetated upper beaches and rocky coastlines

Wetlands Within the Kodiak Launch Complex and Proposed Facility Locations

Kodiak Island, Alaska

Figure 4.1.3-1
SOPs mentioned above for spill prevention, containment, and control measures while transporting equipment and materials would also preclude impacts to wetlands. Steller sea lion critical habitat is outside the area that could be impacted by site preparation activities.

**Operation**

Dual launch activities could potentially occur. Dual launches could result in a slightly larger affected area and longer duration of disturbance to wildlife. Impacts would in some cases be slightly greater than, but similar, to those analyzed below for single launches.

**Vegetation**

Normal GBI launch activities are not expected to significantly impact vegetation. Blast residue would be contained within the silo or close to the launch site in case of a pad GBI launch, minimizing the potential for impacts on vegetation. Launch exhaust products would include hydrogen, hydrogen chloride, aluminum oxide, carbon dioxide, carbon monoxide, nitrogen, water, and chlorine. Nominal launch activities during dry conditions could result in the deposition of very small amounts of aluminum oxide from missile exhaust. Most of this aluminum oxide would be suspended in air and dispersed over extremely large areas; the amount deposited would have little effect. As stated in the air quality section, the concentration levels of exhaust products from a dual launch would be approximately double those of a single launch. Under natural conditions, the chemical is not a source of toxic aluminum; the EPA has determined that non-fibrous aluminum oxide as found in solid rocket motor exhaust is nontoxic (U.S. Department of the Air Force, 1997a). Analysis of launch-related deposition of aluminum oxide after six launches from KLC has not shown it to be harmful to vegetation (Alaska Aerospace Development Corporation, 2002b).

The greatest potential for impacts to vegetation comes from hydrogen chloride deposition. Direct effects could include discoloration, foliage loss, and changes in species composition. Rain within 2 hours of a launch could cause hydrogen chloride to be deposited in small quantities. This chemical, when emitted during solid missile launches for very large flight vehicles (such as the Space Shuttle), is known to injure plant leaves and affect wildlife. However, the potential effect on vegetation from the proposed launches of the much smaller GBIs is expected to be slight. Observation of plant communities at other launch sites such as KTF, Cape Canaveral, and Vandenberg AFB indicate that vegetation continues to thrive in the immediate areas within 150 to 240 meters (492 to 787 feet) of the launch pads. Vegetation sampling conducted in the area near active launch pads at KTF has not indicated that hydrogen chloride emissions from launches conducted during the last 20 years resulted in any lasting effects (U.S. Army Space and Strategic Defense Command, 1993a). No obvious additional needle loss or browning of vegetation adjacent to the launch site has been documented through six launches from KLC (Alaska Aerospace Development Corporation, 2002b).

**Threatened and Endangered Plant Species.** No federally listed candidate, threatened, or endangered plant species have been observed within the boundaries of KLC.

**Wildlife**

**Noise.** Potential noise effects on wildlife can be categorized as auditory and non-auditory. Auditory impacts to marine mammals would consist of injury effects such as eardrum rupture or behavioral impairments such as temporary threshold shift (TTS). Non-auditory effects could
include stress, behavioral changes, and interference with mating or foraging success. The effects of noise on wildlife vary from serious to no effect in different species and situations. Behavioral responses to noise also vary from startling to retreat from favorable habitat. Animals can also be very sensitive to sounds in some situations and very insensitive to the same sounds in other situations. (Larkin, 1996) Informal observation at several launch facilities indicates the increased presence of personnel immediately before a launch tends to cause birds and other mobile species of wildlife to temporarily leave the area that would be subject to the highest level of launch noise. Therefore, no direct physical auditory changes are anticipated.

Wildlife is known to exhibit a startle effect when exposed to short-term noise impacts, such as the launch of a missile. Video camera observations of a wood stork colony located 0.8 kilometer (0.5 mile) south of the Space Shuttle launch pad at Kennedy Space Center showed that birds flew south away from the noise source and started returning within 2 minutes, with a majority of individuals returning within 6 minutes (National Aeronautics and Space Administration, 1997). A rookery at Kennedy Space Center used by wood storks and other species of wading birds located approximately 750 meters (2,461 feet) from a Space Shuttle launch pad continues to be used successfully, even though it has received peak noise levels of up to approximately 138 dB. (American Institute of Aeronautics and Astronautics, 1993) Birds within 250 meters (820 feet) of Titan launch complexes at Cape Canaveral Air Station have shown no mortality or reduction in habitat use. Titan IV vehicles produce noise levels of approximately 170 dB in the immediate vicinity of the launch pad. This attenuates to 125 dB at a distance of 3 kilometers (2 miles) within about 30 seconds following launch. (U.S. Department of the Air Force, 1990b) Noise from Minuteman launches ranges from 98 dBA approximately 4.2 kilometers (2.6 miles) from the launch site to 80 dBA approximately 13 kilometers (8 miles) from the launch site (U.S. Department of the Air Force, 1999). The level of noise for the GBI missile during launch and flight is expected to be less (similar to the 94 dB at 3.0 kilometers [2 miles] from the launch site analyzed in the KLC EA for the Castor 120™) and relatively short in duration.

The KLC EA concluded that, although birds within a 9.7-kilometer (6-mile) radius of the launch pad could be exposed to noise levels above 83 dBA, impacts to birds from launch-related noise would not be severe and would be limited to startle reactions (Federal Aviation Administration, 1996). Peak noise levels in the vicinity of Narrow Cape would be nearly instantaneous, and the entire noise event would last less than 60 seconds. According to monitoring results from the prior six KLC launches, bald eagle habitat use appears to have been unaffected. The Narrow Cape bald eagle nest, which is downrange of the current launch pad, was seasonally occupied and productive during the monitoring period. (Alaska Aerospace Development Corporation, 2002b) Any indication of disturbance to eagle nesting or nesting behavior would be reported immediately to the KLC launch point of contact as specified in the Natural Resources Management Plan (NRMP).

A Biological Opinion (Federal Aviation Administration, 1998) prepared for the FAA and AADC addressed the potential for impacts on the Steller’s eider and short-tailed albatross as a result of operation of the KLC. Interceptor launches would be infrequent, up to five per year over a period of 10 years. Five annual GBI launches would fall within the parameters previously analyzed for KLC and are also not likely to adversely affect listed species. Disturbance to wildlife from single or dual GBI launches would be brief and is not expected to have a lasting impact nor a measurable negative effect on migratory bird populations. Waterfowl would quickly resume feeding and other normal behavior patterns after a launch is completed. Waterfowl driven from preferred feeding areas by aircraft or explosions usually return soon after the
disturbance stops, as long as the disturbance is not severe or repeated (Federal Aviation Administration, 1996).

No evidence has indicated that serious injuries to wildlife have resulted from prior launches, and no long-term adverse effects are anticipated. The brief noise peaks produced by the GBI are comparable to levels produced by close range thunder (120 dB to 140 dB peak). There is no species known to be susceptible to hearing damage following exposure to this noise source (U.S. Department of the Air Force, 2001).

**Emissions.** The KLC area has a high level of rainfall and short steep streams, and small amounts of deposition from launches would be quickly flushed from stream drainages. No long-term impacts to fish in streams or Essential Fish Habitat within the ROI are expected.

Hydrogen chloride, which is emitted during missile launches, is known to affect wildlife. Birds flying through the exhaust plume may be exposed to concentrations that could irritate eye and respiratory systems (Federal Aviation Administration, 1996). However, results of a monitoring program conducted following a Strategic Target System launch from KTF in Hawaii indicated little effect upon wildlife due to the low-level, short-term hydrogen chloride emissions (U.S. Army Space and Strategic Defense Command, 1993a). The program included marine surveys of representative birds and mammals for both pre-launch and post-launch conditions. Studies on representative birds and mammals reviewed in the Final EIS for the Strategic Target System (U.S. Army Strategic Defense Command, 1992) also indicated that low-level, short-term exposure to hydrogen chloride would not adversely affect threatened or endangered species or other wildlife. Aluminum oxide and hydrogen chloride do not bioaccumulate; therefore, no indirect effects to the food chain are anticipated.

**Debris.** In the unlikely event of a launch mishap during single or dual launches, scattered pieces of burning propellant could enter coastal water and potentially affect seabirds, Essential Fish Habitat, and pinnipeds hauled out along the adjacent coastline. Unburned solid fuel is hard and rubber-like, and any ammonium perchlorate would dissolve slowly out of the rubber-like binder, producing ammonia and chlorine that would disperse into the marine waters. Were hazardous materials to leach out of the intercept debris, the great volume of water in the ocean would dilute the contaminant to acceptable levels. The solid fuel’s aluminum oxide is insoluble; in addition, as the fuel slowly dissolves, its outer layers become spongy, further retarding dissolution. Thus, no toxic levels of ammonia, chlorine, or aluminum would be expected. A recent study conducted for the U.S. Air Force (Lang, et al., 2001) measured the amount of perchlorate lost from solid propellant samples immersed in fresh and salt water. From the measurement of the concentration of the perchlorate ion in solution, the mass fraction loss of the propellant sample due to perchlorate leaching was calculated. The results are presented in the KLC Water Resources section, table 4.1.14-2. As shown in the table, it would take approximately 270 days for 90 percent of the perchlorate to leach out of solid propellant that lands in the ocean (at 29°C [84°F]). The perchlorate would be expected to be diluted as it mixes with the surrounding water.

The potential impact to Essential Fish Habitat from nominal launch activities (single and dual) would mainly be from missile debris to waters off the coast. Although debris could affect individuals close to the surface, overall species’ population would not be substantially impacted. The Pasagshak River would not be affected by nominal launch activities and is outside the area likely to be affected by a launch anomaly. Anadromous and marine fisheries would not be
affected by proposed launch activities. Concentrations of toxic materials would be highest in this shallow water and have a greater chance of being ingested by feeding animals. However, the potential for a launch mishap is relatively slight, and in most cases the errant missile would be moving at a rapid rate such that pieces of propellant and other toxic debris would strike the water further downrange. The debris would also be widely scattered, which would reduce the possibility of ingestion. The number of individuals injured or killed would not likely affect overall species’ populations. (U.S. Department of the Air Force, 2001)

Debris impact and booster drops in the BOA off the coast are not expected to adversely affect marine mammal species protected by the Marine Mammal Protection Act of 1972. An early flight termination or mishap could result in debris impact along the flight corridor. Early flight termination could result in widely scattered debris, but the probability of this debris hitting wildlife is remote.

Fire from an early flight termination could impact terrestrial wildlife near the launch site. However, emergency fire-fighting personnel would be on stand-by status for all launch activities as a protective measure.

**Threatened and Endangered Wildlife Species.** The closest Steller sea lion haul-out sites are at Ugak Island, approximately 5 kilometers (3 miles) southeast of KLC, and Gull Point, approximately 16 kilometers (10 miles) southwest of KLC. Ugak Island is used seasonally by the Steller sea lion during the late summer to early fall postbreeding period (Alaska Aerospace Development Corporation, 1999). As addressed in the KLC EA, studies have indicated that launches are likely to produce some level of alarm response in the sea lions using Ugak Island (Federal Aviation Administration, 1996). These responses could range from a heightened state of alertness to total flight of all sea lions from the haulout site.

According to the U.S. Air Force’s QRLV Program EA (U.S. Department of the Air Force, 2001), while it is expected that Steller sea lions hauled out on Ugak Island would react to a launch by entering the water, there is no biologically significant consequence of this behavior because sea lions routinely spend long hours in the water and have been observed returning to land hours later. Since the sea lions do not breed on Ugak Island, there would be no effect on mother–pup bonding. The National Marine Fisheries Service has concurred with the U.S. Air Force’s opinion that predicted launch and overflight noise would have no significant impact on marine mammals. However, AADC has requested a Letter of Authorization from the National Marine Fisheries Service for the incidental harassment take of marine mammals. The USFWS also concurred that no adverse effects would occur to listed species in the ROI of an ait-2 launch. The predicted launch noise level for the GBI would be similar to or less than the level predicted and measured for ait and QRLV launches and as such, no substantial adverse impacts to listed species are expected.

Foraging shorebirds would be subjected to increased energy demands if flushed by the noise, but this should be a short-term, minimal effect. Waterfowl generally show a pronounced startle effect when exposed to noise levels of 95 to 105 dB. It is unlikely that the short-tailed albatross would be impacted by a GBI missile in flight since the trajectory is almost vertical and the missile would reach an altitude of approximately 3,048 meters (10,000 feet) while still over land, approximately 20 seconds after launch.
Although Steller’s eiders rafting off Narrow Cape may be disturbed by the Proposed Action, since they do not breed within the ROI and the disturbance would be minor and infrequent, GBI launches from KLC are not expected to impact breeding or the nesting success of this species.

According to protocol of the KLC Environmental Monitoring Plan, five pre-launch and five post-launch aerial surveys for Steller’s eiders were supposed to be performed for the first five missile launches at KLC. Inclement weather adversely affected this task during all five KLC launches. However, the data collected were sufficient to show that rocket launches were not adversely affecting either species numbers or habitat use patterns of either the eider or of its designated surrogate for monitoring, the harlequin duck (Environment and Natural Resources Institute and Alaska Aerospace Development Corporation, 2002). Steller’s eiders overwinter in the area from mid-October to March. Since it was not known when the launches would take place and if Steller’s eiders would be in the vicinity, the harlequin duck was used as a surrogate during surveys when the eider was not observed in the area. Steller’s eiders were observed during the 1998 ait-1 and 2001 QRLV launches from KLC. No eiders were observed before the ait-1 launch, but 30 were seen minutes after about 0.40 kilometer (0.25 mile) south of Lone Point. The number fluctuated widely during the QRLV monitoring periods. Harlequin ducks were observed during all monitoring periods with no significant differences between pre- and post-launch time periods. Steller’s eider and harlequin duck numbers and use of habitat appeared unaffected by the six prior launches at KLC. (Alaska Aerospace Development Corporation, 2002b)

Environmentally Sensitive Habitat
Nominal GBI launches are not expected to result in impacts to wetlands on KLC. SOPs for spill prevention, containment, and control measures while transporting equipment and materials would also preclude impacts to wetlands.

4.1.3.2.2 Target Missiles
Construction
Vegetation
Alternative 1 would require construction of additional facilities as discussed in section 2.3.1.1. These new facilities would be located adjacent to the proposed GBI silos or launch pad and included within the same fenced area. Existing facilities, such as the existing launch pad, would be modified. No significant impacts to vegetation are anticipated since new construction would occur mainly in upland areas of hairgrass-mixed forb meadow, one of the predominant vegetation types at KLC. This loss of vegetation (approximately 10.5 hectares [26 acres]) would represent only a small portion of the total vegetation available within KLC boundaries.

Threatened and Endangered Plant Species. No federally proposed or listed candidate, threatened, or endangered plant species have been observed within the boundaries of KLC.

Wildlife
Impacts to wildlife from site preparation activities described above under vegetation would be the same as those discussed above for the GBI site preparation.
Threatened and Endangered Wildlife Species. Impacts to threatened and endangered wildlife species from site preparation activities would be the same as those discussed above for the GBI site preparation.

Environmentally Sensitive Habitat
Impacts to environmentally sensitive habitat would be the same as those discussed above for GBI site preparation.

Operation
Dual target launches could potentially occur. Dual launches could result in a slightly larger affected area and longer duration of disturbance to wildlife. Impacts would in some cases be slightly greater than, but nonetheless similar, to those analyzed below for single launches.

Vegetation
As discussed above for GBI launches, observation of plant communities at other launch sites such as KTF, Cape Canaveral, and Vandenberg AFB indicate that vegetation continues to thrive in the immediate areas surrounding launch pads. Vegetation sampling conducted in the area near active launch pads at KTF has not indicated that hydrogen chloride emissions from launches conducted during the last 20 years resulted in any lasting effects (U.S. Army Space and Strategic Defense Command, 1993b). Further studies at KLC have shown no adverse effects to sensitive vegetation following the first six launches (Environment and Natural Resources Institute and Alaska Aerospace Development Corporation, 2002).

Threatened and Endangered Plant Species. No federally proposed or listed candidate, threatened, or endangered plant species have been observed within the boundaries of KLC.

Wildlife
Target missile launches would be infrequent, up to five per year over a period of 10 years. The potential impacts to wildlife from single or dual launches would be similar to those discussed above for GBI launch activities. A Biological Assessment (Federal Aviation Administration, 1998) prepared for the FAA and AADC as part of the construction and operation EA determined that launches of missiles similar to an, QRLV, and Castor 120™ from KLC are not likely to adversely affect listed species, such as the Steller’s eider and short-tailed albatross, or critical habitat. Five annual launches of the proposed target missiles would fall within the parameters analyzed for KLC and are also not likely to adversely affect listed species.

Using noise contours obtained from the monitoring of actual launches at PMRF and superimposing them on the launch site at Kodiak Island, a noise level of 54 dBA at 10,699 meters (35,000 feet) is projected for a Strategic Target System launch. However, this information was obtained by noise monitoring in Hawaii (22 degrees north). Air temperature and humidity affect the propagation of noise. The rate of propagation depends on factors such as distance attenuation, ground attenuation, atmospheric absorption, barrier attenuation, wind effects, and temperature gradient effects. Given atmospheric attenuation with correction for temperature and relative humidity, the actual noise impacts, particularly at the longer distances away from the launch site, might be quite different. Inclement weather precluded the use of a helicopter to set up sound monitors on Ugak Island, and thus no sound data was gathered during the
Strategic Target System launch from KLC in 2001. However, the monitoring report (Alaska Aerospace Development Corporation, 2002b) for the Strategic Target System launch concluded that the noise would likely be similar to ait, QRLV, and Athena missile levels of 80 to 90 dB, which would be audible to pinnipeds. The Peacekeeper missile, which would result in the highest noise levels, uses a military version of the Castor 120™ motor that was analyzed in the KLC EA (Federal Aviation Administration, 1996).

**Threatened and Endangered Wildlife Species.** As addressed in the KLC EA, alarm response in the sea lions using Ugak Island could range from a heightened state of alertness to total flight of all sea lions from the haulout site (Federal Aviation Administration, 1996). Using the noise levels modeled for the Strategic Target System launches at PMRF, the maximum noise levels at the haulout sites on Ugak Island would be approximately 81 dBA, which would be below levels known to disturb waterfowl and wildlife. The monitored noise levels at PMRF indicate a level of 54 dBA at 10,668 meters (35,000 feet). This is significantly less than the 69 dBA indicated by modeling. As such, it is possible, although not assumed that actual sound levels at the haulouts would be less than those indicated by modeling. Using noise levels measured during Peacekeeper missile launches at Vandenberg AFB, the maximum noise levels at the haulout sites on Ugak Island would be approximately 97.7 dBA for a single launch and 100.7 for a dual launch. This would be above the 83 dBA level known to disturb wildlife.

No evidence has indicated that serious injuries would result, and no long-term adverse effects are anticipated. Noise from a recent Athena II launch was measured at 101 dBA at the haul-out sites on Ugak Island. The brief noise peaks produced by the Strategic Target System, Peacekeeper target, and other proposed target missiles are comparable to levels produced by close range thunder (120 dB to 140 dB peak). There is no species known to be susceptible to hearing damage following exposure to this noise (U.S. Department of the Air Force, 2001). The predicted launch noise level for the Strategic Target System of 81 dBA would be less than the level predicted and measured for the QRLV-1 (87.2 dBA at Ugak Island) launch and, as such, no substantial adverse impacts to listed species are expected.

To date, no indications of disturbance to the sea lions from survey activities on Ugak Island, which are done in full view of beached sea lions, have been identified. Safety crews and other personnel are briefed on the survey procedures as well as harassment guidelines established by the National Marine Fisheries Service to minimize harassment. The GMD ETR program would adhere to the terms and conditions of the pending harassment/take permit from the National Marine Fisheries Service.

*Environmentally Sensitive Habitat*

Impacts to environmentally sensitive habitat would be similar to those discussed above for GBI launches.

**4.1.3.2.3 In-Flight Interceptor Communication System Data Terminal Construction**

*Vegetation*

The IDT and road at Sites 1, 2, and 3 would require disturbance of approximately 5.9 hectares (14.6 acres) with a fenced area of approximately 3.2 hectares (8 acres). The COMSATCOM
(figure 2.1.3-2) would require a footprint of approximately 0.10 hectare (0.25 acre) within a fenced area of approximately 2.8 hectares (7 acres) to accommodate the COMSATCOM and equipment. The minimal requirements include a concrete base for the COMSATCOM, an all-weather road to the site, and a prepared surface around the site at least 4.6 meters (15 feet) wide.

Construction would occur mainly in upland areas of hairgrass-mixed forb meadow, one of the predominant vegetation types at KLC. This loss of vegetation would represent only a small portion of the total vegetation available within KLC boundaries.

**Threatened and Endangered Plant Species.** No federally proposed or listed candidate, threatened, or endangered plant species have been observed within the boundaries of KLC.

**Wildlife**
Impacts to wildlife from ground disturbance and equipment noise would be similar to those discussed above for GBI site preparation.

**Threatened and Endangered Wildlife Species.** No impacts to threatened and endangered seabirds or marine mammals are anticipated from construction activities at the inland sites proposed for use for the IDT or COMSATCOM.

**Environmentally Sensitive Habitat**
No wetlands or other sensitive habitat would be disturbed during construction and installation of the IDT.

**Operation**

**Vegetation**
No impacts to vegetation would result from operation of the IDT or COMSATCOM.

**Threatened and Endangered Plant Species.** No federally proposed or listed candidate, threatened, or endangered plant species have been observed within the boundaries of KLC.

**Wildlife**
During normal operations, the IDT would not transmit except for a few minutes during annual testing of the equipment and during the GBI flight tests. Given the short duration of transmission, no adverse impacts to biological resources are anticipated. Most operational impacts to wildlife from the IDT would come from security lighting and noise from electrical generators required for the site. The lighting and noise could encourage species less tolerant of these disturbances to avoid the area. Generator noise could range from 80 to 85 dBA at up to 105 meters (344 feet). These noise levels would only occur a couple of hours a week during maintenance activities required for backup generators or continuously if no commercial power is available.
COMSATCOM primary power is from a commercial source with backup power provided by generator. Communication cable to the Launch Control Center would be required. Equipment would be housed in a military van, a small building, or an existing adjacent facility if available.

**Threatened and Endangered Wildlife Species.** No adverse impacts to threatened and endangered wildlife species are anticipated. As stated above, most operational impacts to wildlife from the IDT would come from security lighting and noise from electrical generators required for the site. Generator noise could range from 80 to 85 dBA at up to 105 meters (344 feet), which would not adversely affect species offshore.

*Environmentally Sensitive Habitat*

No adverse impacts to environmentally sensitive habitat are anticipated from security lighting or generator noise due to operation of the IDT and COMSATCOM.

### 4.1.3.2.4 Sensors

There are currently no sensors permanently located at KLC. Proposed sensor use at one location on KLC and at one out of seven alternate sites throughout south-central or southwest Alaska would require that sensors be transported to these locations. An existing disturbed area would be used to minimize the potential for impacts. Mobile sensors necessary to support GMD ETR activities would also be located on existing disturbed areas. No impacts to biological resources are anticipated.

### 4.1.3.2.5 TPS-X Radar

**Construction**

*Vegetation*

Installation of the TPS-X radar would require disturbance to 0.3 hectare (0.8 acre) of land on KLC for placement of a concrete pad. Construction would occur mainly in upland areas of hairgrass-mixed forb meadow, one of the predominant vegetation types at KLC. This loss of vegetation would represent only a small portion of the total hairgrass-mixed forb meadow habitat available within KLC boundaries.

**Threatened and Endangered Plant Species.** No federally proposed or listed candidate, threatened, or endangered plant species have been observed within the boundaries of KLC. Thus no impacts to threatened or endangered species would result from installation of the TPS-X radar.

*Wildlife*

Impacts from ground disturbance and equipment noise could temporarily displace terrestrial wildlife as discussed for GBI site preparation. Additional similar habitat is available on KLC to accommodate roosting, nesting, and feeding needs.

**Threatened and Endangered Wildlife Species.** No impacts to threatened and endangered seabirds or marine mammals are anticipated from construction activities at the inland site proposed for use for the TPS-X radar.
Environmentally Sensitive Habitat
No wetlands or other sensitive habitat would be disturbed during construction and installation of the TPS-X radar.

Operation
Vegetation
Operation of the Prime Power Unit would require refueling operations. The fuel tank would be filled from a fuel truck, as necessary. Impermeable ground covering material and spill containment berms would be placed for containment of fuel during fueling operations. Spill control procedures would be established using KLC’s approved SOPs, and spill control kits would be present at the site in the unlikely event of a fuel leak or spill.

The Cooling Equipment Unit is a closed system, and no emissions of the ethylene glycol solution are planned. However, because of the remote potential for leaks or spills during system hook-up, or the possibility of ruptured hoses or accidental disconnection, impermeable ground cover would be in place as was described for the Prime Power Unit.

Operation of the TPS-X radar would not result in impacts to vegetation since impermeable ground covering material and spill containment berms would be placed for containment of fuel during fueling operations.

Threatened and Endangered Plant Species. No federally proposed or listed candidate, threatened, or endangered plant species have been observed within the boundaries of KLC. Thus no impacts to threatened or endangered species would result from operation of the TPS-X radar.

Wildlife
The Prime Power Unit is a self-contained trailer with a noise-dampening shroud that would minimize the potential for diesel generator noise impacts.

In terms of the potential for EMR impacts to wildlife, the power densities emitted from the TPS-X radar are unlikely to cause any biological effects in animals or birds. The TPS-X radar is not expected to radiate lower than 5 degrees above horizontal, which would preclude EMR impacts to terrestrial species from either operation of the TPS-X radar during flight tests or later during proposed tactical testing.

The potential for main-beam (airborne) exposure thermal effects to birds exists. In terms of the potential for EMR impacts on wildlife, the Final Ground-Based Radar (GBR) Family of Radars EA (U.S. Army Program Executive Office, Global Protection Against Limited Strikes (GPALS), 1993) analyzed potential impacts on wildlife from EMR. This EA determined that several factors significantly reduce the potential EMR exposure for birds and other wildlife. The radar main beam would normally be located at least 2 degrees above horizontal, which limits the probability of energy absorption by surface-oriented wildlife. The radar beam would normally be in motion, making it extremely unlikely that a bird would remain within the most intense area of the beam for any considerable length of time. The size of the beam is relatively small, which further
reduces the probability of bird species remaining within this limited region of space, even if the beam were still. (Ballistic Missile Defense Organization, 2000)

The analysis methods used to evaluate potential effects of RF radiation on birds is the MPEL, which defines the maximum time-averaged RF power density allowed for uncontrolled human exposure (and by extrapolation, to birds and other species). The MPEL method is independent of body size or tissue density being exposed. Analysis conducted during preparation of the GBR EA (U.S. Army Program Executive Office, Global Protection Against Limited Strikes (GPALS), 1993) was based on a conservative approach of limiting the microwave energy absorption rate on the Aplomado falcon (*Falco femoralis*), a bird listed as endangered by the USFWS and the State of New Mexico. The energy absorption rate was based on the falcon remaining continuously within the main beam of the ground-based radar. The absorption rate was then compared to the bird’s resting metabolic rate. The analysis indicated power densities would have to exceed 42 mW/cm² to affect the falcon. Power densities of 38 to 61 mW/cm² have been determined necessary to affect other birds weighing up to 3.5 kilograms (7.7 pounds).

The analyses were based on the conservative assumption that the energy absorption rate of a bird’s body was equal to its resting metabolic rate and that this may pose a potential for an adverse effect. Birds in general typically expend energy at up to 20 times their resting metabolic rates during flight. Since birds are not likely to remain continuously within the radar beam and the power density is not expected to exceed levels stated above that could impact birds, the likelihood of harmful exposure is remote. (Ballistic Missile Defense Organization, 2000)

**Threatened and Endangered Wildlife Species.** The potential for impacts to threatened and endangered seabirds would be the same as that discussed above for wildlife. The TPS-X radar is not expected to radiate lower than 5 degrees above horizontal, and since marine mammals would normally be found below the surface of the water, this signal height would be safely above any surfacing mammals. RF radiation does not penetrate the surface of water to any great degree. The power density level just below the surface of the ocean would not exceed the permissible exposure level for uncontrolled environments. (U.S. Department of the Navy, 2002a) No adverse impacts would occur to whales, other marine mammals, or sea turtles at least 1.3 centimeters (0.5 inch) below the surface. It is also highly unlikely that an individual would be on or substantially above the surface of the water for a significant amount of time within the main beam or side lobe areas when the TPS-X radar would be operating. No impacts to marine mammals offshore are expected as a result of proposed radar operation on KLC since these species would normally be found in the ocean outside the 150-meter (492-foot) personnel exclusion zone. For these reasons, no effects are anticipated on the humpback whale, other marine mammals, or sea turtles that might be present in the vicinity. Therefore, no further action regarding whales is required pursuant to the Endangered Species Act and the Marine Mammal Protection Act.

*Environmentally Sensitive Habitat*

No wetlands or other sensitive habitat would be adversely affected during operation of the TPS-X radar.
4.1.3.3 Alternative 2
No GBI-related construction would be required at KLC under Alternative 2 since GBI launches would occur from Vandenberg AFB and RTS instead of KLC and RTS. Target launch-related impacts would be identical to those described under Alternative 1. As discussed in Alternative 1, proposed sensor use at one location on KLC and at one out of seven alternate sites throughout south-central or southwest Alaska would require that sensors be transported to these locations. Mobile sensors necessary to support GMD ETR activities would be located on existing disturbed areas. No impacts to biological resources are anticipated.

4.1.3.4 Alternative 3
For the purposes of the discussion at KLC, the construction and flight impacts for Alternative 3 would be as described above for Alternative 1.

4.1.3.5 Cumulative Impacts
Construction associated with the GMD ETR program would result in the loss of up to approximately 34 hectares (85 acres) of meadow and shrubland within KLC boundaries. When combined with past disturbed areas the total would equal approximately 52 hectares (128 acres). This cumulative total represents approximately 3.5 percent of the total available acreage of KLC. Similar habitat is available adjacent to the proposed locations and no federally threatened or endangered plants have been identified within KLC boundaries. No cumulative changes in plant community composition or structure have been identified at other active launch locations such as Vandenberg AFB and Kennedy Space Center.

The KLC EA indicated no significant impact to biological resources from nine annual launches (Federal Aviation Administration, 1996). It is not likely that the Proposed Action of up to five launches (GBI and/or target) in conjunction with other currently planned or anticipated launches at KLC would exceed nine launches per year, the level of activity analyzed in the KLC EA. According to the QRLV EA (U.S. Air Force, 2001), multiple failures at the same point in flight during launches would be required to cumulatively affect Essential Fish Habitat or other sensitive biological resources. This scenario is highly unlikely. Combined activities would be performed at different times and locations. No cumulative impacts from launches proposed for the GMD ETR program are anticipated.

4.1.3.6 Mitigation Measures
No biology mitigation measures are proposed for the GMD ETR activities at KLC. GMD ETR proposed activities would adhere to the terms and conditions imposed by the National Marine Fisheries Service on AADC.

4.1.4 CULTURAL RESOURCES—KODIAK LAUNCH COMPLEX
Potential impacts on archaeological and historic resources may result from construction; ground-clearing; off-road traffic activities; sound pressure damage; increased human presence in archaeologically sensitive areas; and/or alteration, modification, renovation, or demolition of existing potentially significant facilities and other activities.
Only those cultural resources determined to be potentially significant under existing legislation are subject to protection from adverse impacts resulting from the Proposed Action or its alternatives. To be considered significant, cultural resources must meet one or more of the criteria established by the National Park Service that would make that resource eligible for inclusion in the National Register. The term eligible for inclusion includes both properties formally determined as such and all other properties that meet the listing criteria. Sites which have not yet been formally evaluated are considered potentially eligible and, as such, are afforded the same consideration as formally nominated properties. Prehistoric (usually referred to as archaeological), historic, or traditional significant cultural resources are referred to as historic properties.

An undertaking is considered to have an effect on a historic property when it may alter characteristics of the property that may otherwise qualify the property for inclusion in the National Register. An effect is considered to be adverse when it diminishes the integrity of the property’s location, design, setting, materials, workmanship, feeling, or association. Adverse effects on historic properties include but are not limited to:

- The physical destruction, damage, or alteration of all or part of the property
- Isolation of the property from, or alteration of the character of, the property’s setting when that character contributes to the property’s qualification for the National Register
- Introduction of visual, audible, or atmospheric elements that are out of character with the property or alter its setting
- Neglect of a property resulting in its deterioration or destruction
- Transfer, lease, or sale of the property

4.1.4.1 No Action Alternative

Missile Defense Agency

Under the MDA’s No Action Alternative, launches would continue to occur at KLC although the GMD ETR would not be established and GBI and target launch scenarios would not be tested under more operationally realistic conditions. These launches could include missions in support of the GMD program. KLC would continue to operate as a licensed launch facility, and, as concluded in the KLC EA (Federal Aviation Administration, 1996), no cultural impacts would be anticipated.

Federal Aviation Administration

Under the FAA’s No Action Alternative, the launch site operator license for KLC would not be renewed and no launches would be allowed to occur from KLC after September 2003. Therefore, there would be no impacts to cultural resources from launches at KLC.
4.1.4.2 Alternative 1

4.1.4.2.1 Ground-Based Interceptors

Construction
The proposed activities under Alternative 1 would require construction of numerous facilities as described in section 2.3.1.1. Potential total disturbed areas due to construction are identified in table 2.3.1-3.

Prehistoric and Historic Archaeological Resources
Previous archaeological surveys have indicated that cultural resources are not present in the upland areas occupied by KLC. As project details are further delineated, additional archaeological surveys may be required to verify the absence of sites within the area of potential effect. Should cultural resources be found during the course of any GMD ETR activity, all activities would cease in the area and the proper authorities would be notified. Subsequent actions would follow the guidance provided; therefore, no impacts to archaeological resources are anticipated.

Large GBI components may need to be brought into KLC by barge, as described in section 2.3.1. Figure 2.3.1-1 shows the proposed barge landing sites. If it is determined that a barge landing is required, one of the three potential sites would be selected for use. At that time, an archaeological survey would be conducted to verify the presence of the reported sites described in section 3.1.4.2 and to determine if there are previously unreported sites within the area of potential effect.

Historic Buildings and Structures
There are no structures in the area currently occupied by KLC infrastructure that are listed on the National Register of Historic Places. No construction activities or building modifications are expected to have an effect on any historic properties.

Native Populations/Traditional Resources
The 1994 survey of the KLC area showed no signs of traditional resources within the ROI. Therefore, no impacts to traditional resources are anticipated. As mentioned above, should cultural resources be found during the course of any GMD ETR activity, all activities would cease in the area and the proper authorities would be notified. Subsequent actions would follow the guidance provided.

Paleontological Resources
There is the potential that shallow-water marine invertebrate fossils would be disturbed during construction of the GBI facilities. However, these fossils are extremely common throughout the areas in and around KLC, and significant impacts to these resources are not anticipated.

Operation
Proposed GBI operations for Alternative 1 at KLC would consist of single and dual interceptor launches.
**Flight Activities**
Personnel would be informed of the sensitivity of cultural resources and the types of penalties that could be incurred if sites are damaged or destroyed. The only potential impacts to cultural resources would be as a result of debris generated by a test failure. However, the possibility of this occurring is extremely remote.

**Post-Flight Activities**
Debris recovery from unsuccessful launches at KLC is the responsibility of the user and is closely monitored by AADC. If required, debris recovery on land may involve the use of helicopters and off-road vehicles. Recovery of missile and missile components after unsuccessful launches would be conducted in accordance with KLC procedures. If the potential exists to disturb cultural resources during debris recovery activities, recovery efforts would be coordinated with KLC range representatives and agencies to develop appropriate mitigation measures to avoid impact to sensitive resources and to restore natural areas as necessary following debris recovery efforts.

4.1.4.2.2 **Target**

**Construction**
Under Alternative 1, site preparation activities overlap somewhat with GBI facilities. Since no cultural resources have been identified within the construction footprint, there would be no adverse effects to cultural resources due to target facility construction.

**Operation**
Proposed target operations for Alternative 1 at KLC would include single and dual target launches.

**Flight Activities**
Target launches, from a cultural resources standpoint, would be similar to an interceptor launch. Personnel would be informed of the sensitivity of cultural resources and the types of penalties that could be incurred if sites are damaged or destroyed. The only potential impacts to cultural resources would be as a result of debris generated by a test failure. However, the possibility of this occurring is extremely remote.

**Post-Flight Activities**
If required, debris recovery on land may involve the use of helicopters and off-road vehicles. Recovery of missile and missile components after unsuccessful launches would be conducted in accordance with KLC procedures. If the potential exists to disturb cultural resources during debris recovery activities, recovery efforts would be coordinated with KLC range representatives and agencies to develop appropriate mitigation measures to avoid impact to sensitive resources and to restore natural areas as necessary following debris recovery efforts.
4.1.4.2.3 In-Flight Interceptor Communication System Data Terminal

Construction

Under Alternative 1, proposed construction would include disturbance of 8.7 hectares (21.6 acres) for an IDT and COMSATCOM. Cultural resources have not been identified within the areas and therefore there would be no adverse effects to cultural resources from IDT and COMSATCOM construction.

Operation

Proposed activities for Alternative 1 at KLC include IDT and COMSATCOM operations.

Flight Activities

IDT and COMSATCOM operations are not expected to adversely impact cultural resources. The nature of the operation of these systems combined with the lack of existing cultural resources would result in no impacts.

4.1.4.2.4 Sensors

Proposed sensor use at one location on KLC and at one or more out of seven alternate sites throughout south-central or southwest Alaska would require that sensors be transported to these locations. Mobile Systems would likely be parked at pre-existing parking areas and no ground disturbance would be required. Therefore, impacts to cultural resources are not anticipated.

Flight Activities

Operation of sensors of this nature is not expected to produce any short- or long-term effects to cultural resources. Personnel would be informed of the sensitivity of cultural resources and the types of penalties that could be incurred if sites are damaged or destroyed.

4.1.4.2.5 TPS-X

Construction

The installation of the TPS-X at KLC would require the construction of a pad for the 38- by 58-meter (125- by 190-foot) hardstand and disturbance of approximately 0.3 hectare (0.8 acre). The potential TPS-X location would be the same as the potential IDT site south of the Loran-C Station. Previous archaeological surveys have indicated that cultural resources are not present within the upland areas occupied by KLC. As project details are further delineated, additional archaeological surveys may be required to verify the absence of sites within the area of potential effect. Should any culturally related resources be found during the construction of the TPS-X radar, all construction activities would cease and the proper authorities would be notified. Therefore, impacts to cultural resources are not anticipated.

Operation

Operation of the Prime Power Unit would require refueling operations. The fuel tank would be filled from a fuel truck, as necessary. Impermeable ground covering material and spill containment berms would be placed for containment of fuel during fueling operations. Spill
control procedures would be established in accordance with KLC’s approved SPCC SOPs, and spill control kits would be present at the site in the unlikely event of a fuel leak or spill.

The Cooling Equipment Unit is a closed system, and no emissions of the ethylene glycol solution are planned. However, because of the remote potential for leaks or spills during system hook-up, or the possibility of ruptured hoses or accidental disconnection, impermeable ground cover would be in place as was described for the Prime Power Unit.

Because impermeable ground covering and spill containment berms would be employed and due to the lack of located resources in the area, impacts to cultural resources are not anticipated from the refueling of the Prime Power Unit.

In terms of the potential for EMR impacts to cultural resources, the power densities emitted from the TPS-X radar are unlikely to cause any damaging effects to cultural resources. The TPS-X radar is not expected to radiate lower than 5 degrees, which would preclude EMR impacts to terrestrial artifacts from either operation of the TPS-X radar during flight tests or later during proposed tactical testing. Therefore, the operation of the TPS-X radar is not expected to have any adverse impacts to cultural resources.

4.1.4.3 Alternative 2

4.1.4.3.1 Target

Construction
Proposed target construction for Alternative 2 at KLC is identical to that described in Alternative 1.

Operation
Potential impacts from proposed target operations for Alternative 2 at KLC would be identical to that described in Alternative 1.

4.1.4.3.2 Sensors

Construction
The mobilization and setup activities for mobile telemetry systems at remote locations throughout Alaska would be identical to that described for Alternative 1 and would have negligible adverse impacts.

Operation
The operation of mobile telemetry system would be identical to activities described under Alternative 1; however, the system would be operated for target launches only. No operational aspect of the system poses the potential for adverse effects to cultural resources.
4.1.4.4  Alternative 3

Alternative 3 would be identical to Alternative 1 at KLC. Because Alternative 1 includes GBIs, targets, and all associated facilities, the construction and flight impacts for Alternative 3 would be as described for Alternative 1.

4.1.4.5  Cumulative Impacts

The KLC EA indicated no significant impact to cultural resources for nine annual launches (Federal Aviation Administration, 1996). It is not likely that the Proposed Action of up to five launches (GBI and/or target) in conjunction with other currently planned or anticipated launches at KLC would exceed nine launches per year, the level of activity analyzed in the KLC EA. Approximately 17 hectares (43 acres) or 1.1 percent of KLC’s 1,504 hectares (3,717 acres) have previously been disturbed. The proposed action could potentially affect up to 26 hectares (64.2 acres). The cumulative disturbed acreage of the existing and proposed actions would be approximately 43 hectares (106 acres) or 2.9 percent of the total acreage of KLC. No other activities have been identified at KLC that, when combined with the past and proposed action would result in cumulative impacts to cultural resources.

4.1.4.6  Mitigation Measures

No cultural resources mitigation measures are proposed for the GMD ETR activities at KLC at this time. As project details are further delineated, coordination would occur with the Alaska State Historic Preservation Officer to ensure that cultural resources would be protected.

4.1.5  GEOLOGY AND SOILS—KODIAK LAUNCH COMPLEX

The proposed program activities have the potential to increase soil erosion due to construction and vehicle traffic on unpaved roads. GBI and target missile launches could affect the chemical composition of site soils. Construction activities could have a direct short-term affect on the availability of selected geologic resources, such as aggregate for road base and high-strength concrete. Program support facilities, IDT, sensors, radar, and other critical equipment would be potentially subject to strong vibratory ground motions from earthquakes and volcanic ash falls. Active fault segments could potentially result in surface ruptures during large earthquakes resulting in damaging facilities and infrastructure along the trace.

4.1.5.1  No Action Alternative

Missile Defense Agency

Under the MDA's No Action Alternative, launches would continue to occur at KLC, although the GMD ETR would not be established and GBI and target launch scenarios would not be tested under more operationally realistic conditions. Maintenance or construction projects proposed by AADC at KLC which would result in ground disturbance would be subject to environmental review by the FAA if that action were a modification to the facilities, facility layout, and operations described in the launch site operator license. KLC is located within a seismically active area, but existing facilities have been designed and constructed to Seismic Zone IV standards (Uniform Building Code, 1994) and should withstand probable levels of vibratory ground motion at the site (appendix D). Further, KLC existing facilities are situated at elevations
that are greater than the limits of maximum wave run-up from a probable tsunami event (seismically generated sea wave).

KLC would continue to conduct launches as specified in the KLC launch site operator license. The KLC EA concluded that there would be no measurable long-term changes in the pH of soils from the exhaust deposition of up to nine launches of the Athena-2, using a Castor 120™ motor for propulsion, per year (Federal Aviation Administration, 1996). Environmental monitoring efforts to date have not indicated any adverse changes in soil chemistry resulting from launches. No adverse changes to soil chemistry would be anticipated under the MDA’s No Action Alternative at KLC.

Federal Aviation Administration

Under the FAA’s No Action Alternative, the launch site operator license for KLC would not be renewed and no launches would be allowed to occur from KLC. Therefore, there would be no impacts to geology and soils from launches at KLC.

4.1.5.2 Alternative 1

4.1.5.2.1 Ground-Based Interceptors

Construction

Alternative 1 would require construction of numerous facilities as described in section 2.3.1.1. Fiber optic cable would be pulled through existing conduit in the fiber-optic cable network, however, additional trenching would be required for selected facilities that are proposed outside of the established backbone. The probable area of soil disturbance for all GBI-related facilities and roads would be approximately 14.4 hectares (35.5 acres), owing largely to grubbing and clearing of vegetation within the perimeter fencing, foundation excavation, stockpile, and equipment maneuver areas.

Minor effects to soils are likely to occur because of the proposed site preparation and construction activities. Most proposed facilities and service roads would be situated at or near local topographic highs in mildly sloping terrain, with little potential for sheet flooding or uncontrolled surface water runoff from higher elevations. The upland soils are generally well drained and not considered to be sensitive to erosion on slopes of less than 7 percent (U.S. Department of the Air Force, 2001). AADC would obtain and review necessary definitive information on surface faulting in the vicinity of the proposed GBI facilities. In making final siting and design determinations, AADC would incorporate all appropriate standards specified by its licensed and bonded A&E contractor. The KLC Natural Resource Management Plan (Alaska Aerospace Development Corporation, 1998) would be referred to for managing laydown areas and topsoil piles before construction, and after construction for providing direction on the disposition of excess topsoil and the selection of plants for revegetation. Best Management Practices would be used for erosion and sediment control. Such Best Management Practices could include storm water diversions, sediment barriers, stream protection, dust palliatives, and other stabilization treatments.

Alternative 1 would not significantly deplete sources of construction material in the region. Tertiary bedrock (the Narrow Cape Formation) underlies most of the KLC property and is suitable as general construction fill material and is readily available (Alaska Aerospace
Development Corporation, 1995b). Surface aggregates have previously been hauled from Pasagshak Point to provide surface course materials over the local sandstone. Sources of structural fill material may need to be imported from existing commercial source areas near the City of Kodiak. Indirect short-term impacts could be created from increased dust and traffic.

Operation

Alternative 1 would result in up to five missile launches per year from KLC over the duration of the test program. GBI launch activities may present minor adverse impacts to local soils due primarily to booster stage exhaust emissions during a nominal test launch, or from unburned or partially burned propellant fuels in the event of a terminated flight. Each EKV would contain approximately 7.5 liters (2.0 gallons) of liquid fuel (monomethylhydrazine) and 5.5 liters (1.5 gallons) of liquid oxidizer (nitrogen tetroxide). Preloaded fuel and oxidizer tanks would be installed on the EKV, so there would be no need for onsite fueling of the GBI and thus no anticipated adverse effect from direct contamination of soils from spills at the Missile Assembly Building, GBI silo, or launch pad.

During a nominal launch, the GBI booster would primarily emit hydrogen chloride, aluminum oxide, chlorine, carbon monoxide, carbon dioxide, hydrogen, nitrogen, oxygen, and water. Most hazardous constituents of the propellant would be completely consumed during the launch. Under this scenario, only small amounts of hydrogen chloride and aluminum oxide emissions would be anticipated to directly contact the soil adjacent to the launch pad and downwind of the flight corridor.

No adverse changes to soil chemistry are predicted to occur as a result of hydrogen chloride or aluminum oxide deposition from interceptor launches. As described in section 4.1.1, soil deposition of hydrogen chloride is expected to be minimal because relatively small amounts of hydrogen chloride are released in the booster ground cloud and the emissions disperse rapidly. Because KLC is near the ocean, a significant fraction of the gas phase hydrogen chloride would condense in the marine aerosol (U.S. Air Force, 1997). This would lower the gas phase concentrations, but would also retard the ground deposition and would re-evaporate in several minutes, leaving downwind concentrations unchanged. Deposition of hydrogen chloride was analyzed for the Athena-2 launch vehicle and it was concluded that there would be no measurable increase in soil pH for up to nine launches per year (Federal Aviation Administration, 1996). The Athena-2 (figure 2.1.2-1) uses a Castor 120™ first stage that is larger than the GBI. The proposed GBI configuration (table 4.1.1-10) has less solid rocket fuel capacity than the Athena-2 and, therefore, would likely produce lower exhaust emissions.

Ground deposition of aluminum oxide is expected to be small and result in minor impacts. Soil deposition of measurable levels of aluminum oxide from a moving exhaust cloud is predicted to be negligible (Pacific Missile Range Facility, Barking Sands, 1998). Typically, no solid propellant missile launches would occur during rain, and the launch system would not use a water deluge system for cooling and noise suppression (a deluge system could increase the potential for ground deposition). The EPA has determined that nonfibrous aluminum oxide as found in solid rocket motor exhaust, is nontoxic. (U.S. Army Space and Strategic Defense Command, 1994)

For analysis of dual GBI launches, the exhaust products from a nominal launch are conservatively estimated to be twice the level of a single launch. The analysis of dual launches
under air quality (section 4.1.2.1) concluded that hydrogen chloride emissions would not exceed U.S. Air Force exposure limits and that the level of aluminum oxide would be expected to remain within the non-criteria pollutant level. Therefore, it is not expected that dual launches would result in significant ground deposition of either pollutant.

In the unlikely event of an on-pad fire or catastrophic missile failure over land, most or all of the solid propellant fuel would likely burn up before being extinguished. Any remaining fuel would be collected and disposed of as a hazardous waste. The total quantities of hydrogen chloride and aluminum oxide released in an on-pad failure of a GBI would be equivalent to that released during a nominal launch of an Athena-2. Therefore, an on-pad failure is not expected to result in significant ground deposition of either pollutant.

Small quantities of hydrazine in the EKV could also be released. Hydrazine is heavier than air and, if not oxidized when airborne, would react and/or possibly ignite with the porous earth or would form dimethylamine and oxides of nitrogen. All of these substances are soluble in water. Airborne nitrogen dioxide would return to earth as nitric acid rains in precipitation events. (U.S. Army Space and Strategic Defense Command, 1995)

Likewise, the nitrogen tetroxide that reached the ground would also react with calcium carbonate soil to form calcium nitrates. Calcium nitrate, a strong oxidizer, is a dangerous fire risk in contact with organic materials. Therefore, depending on the amount of the propellant and/or oxidizer released, soils contaminated with these liquid propellants may require removal to prevent subsequent fires or explosions. The relatively small amount of nitrogen tetroxide on the EKV (5.5 liters [1.5 gallons]) would indicate that such a release would pose a relative minor adverse affect on the site and vicinity soils. Calcium nitrate is also water soluble, so it is anticipated that any residual material or unreacted fuel would be washed into surface drainages and directly out to sea.

4.1.5.2.2 Target

Construction

Alternative 1 would require construction of new facilities as described in section 2.3.1.1. In addition, there would be an addition/alteration to an existing launch pad (Launch Pad-1). Most of the adversely affected soil area related to target facilities would be encompassed by GBI site preparation activities.

The environmental considerations and consequences of constructing target facilities at KLC are similar to those discussed for GBI facilities in section 4.1.5.2.1.

Operation

Alternative 1 could result in up to five target missile launches per year from KLC over the duration of the test program. Unlike GBI, target missiles could consist of several different missile types and configurations including Strategic Target System, Minuteman II Target, Peacekeeper Target, and Trident I (C4) Target. All target missiles noted use solid propellants for the booster stage and, as such, during nominal launch scenarios would emit exhaust products from solid fuels at the launch pad and along the flight path. The minor effects to KLC soils anticipated from solid fuel emissions are discussed in section 4.1.5.2.1.
The Peacekeeper Target is the largest of these target vehicles and consists of both solid and liquid fueled stages. For purposes of analysis, Peacekeeper Target also represents the most difficult of the target missiles to handle, store, and refuel. Target missiles would be stored and assembled in missile storage facilities, and liquid fuels and oxidizers would be stored in separate fuel storage facilities. Each of these facilities would have the capability to contain unanticipated releases of liquid fuels, as well as procedures for reacting to such spills to ensure that local soils are not contaminated.

In the highly unlikely event of an on-pad fire or terminated launch, the Peacekeeper Target could potentially release 76,848 kilograms (169,420 pounds) of solid propellant, and 1968 liters (520 gallons) of liquid fuel. As discussed in section 4.1.5.2.1, most of the solid propellant would be expected to burn upon impact with the ground. Unburned components of the fuel would be removed and treated as hazardous waste.

The total quantity of aluminum oxide and hydrogen chloride released in an on-pad failure of a Peacekeeper target would be approximately 26,900 kilograms (59,300 pounds) and (12,300 kilograms (27,100 pounds) respectively. This would be equivalent to that released during three nominal launches of an Athena-2 missile. As discussed in section 4.1.1.2.2, the airborne concentrations of the pollutants would be higher than during a nominal launch, but would return to ambient levels within several hours. Modeling results from the testing of much larger Advanced Solid Rocket Motor program vehicles, which output 196,357 kilograms (432,885 pounds) of aluminum oxide and 115,572 kilograms (254,789 pounds) of hydrogen chloride concluded that there would be no significant impacts to soils as a result of aluminum oxide and hydrogen chloride deposition (National Aeronautics and Space Administration, 1990). Most of the aluminum oxide would be suspended in the air and dispersed over extremely large areas, and the amount of aluminum oxide deposited on the ground would not significantly change the soils chemistry. The hydrogen chloride, under the most conservative rain conditions, would be buffered by the soil and would not significantly change the soil’s pH (National Aeronautics and Space Administration, 1990). The soils in the ROI are expected to have similar alkalinity and a similar buffering capability. Due to the much smaller emission quantities of aluminum oxide and hydrogen chloride from a highly unlikely on-pad accident of a Peacekeeper target, impacts are expected to be minor.

In the highly unlikely case of an on-pad accident, the liquid fuel (hydrazine) from the fourth stage of the Peacekeeper target is heavier than air and, if not oxidized when airborne, would react and/or possibly ignite with the porous earth or would form dimethylamine and oxides of nitrogen. All of these substances are soluble in water. Airborne nitrogen dioxide would return to earth as dilute nitric acid rains in precipitation events. (U.S. Army Space and Strategic Defense Command, 1995)

4.1.5.2.3 In-Flight Interceptor Communication System Data Terminal Construction

Alternative 1 would require construction of an IDT (one of three optional sites), COMSATCOMs (one of four optional sites), and connecting roads and cables. The probable disturbed area from site preparation would be approximately 5.9 hectares (14.6 acres). Soil disturbance from site preparation activities would be relatively minor and short in duration. Site preparation and construction activities would follow established procedures and Best Management Practices as previously described in section 4.1.5.2.1. AADC would obtain and review necessary definitive
information on surface faulting in the vicinity of the proposed IDT facilities. In making final siting and design determinations, AADC would incorporate all appropriate design standards specified by its licensed and bonded A&E contractor. All IDT facilities would be constructed outside of existing 100-year floodplains and beyond established limits for tsunami wave run-up for a maximum probable tsunami event. Except for localized soil compaction in the construction area, indirect and long-term impacts to the soils resulting from IDT construction would not be anticipated.

**Operation**

Operation of the IDT would have no direct, short- or long-term effect on surrounding geology or soils. Long-term indirect effects, primarily from vehicle traffic for support and maintenance, would result in very minor soil compaction and dust generation on gravel access roads.

### 4.1.5.2.4 Sensors

**Construction**

Alternative 1 would require a single gravel pad area out of seven alternate locations for mobile telemetry. An existing disturbed area would be utilized, and therefore soil disturbance from site preparation activities would be relatively minor and short in duration. Site preparation activities would follow Best Management Practices for soil management and erosion control (see section 4.1.5.2.1).

**Operation**

Operation of the sensors would have no direct or indirect, short- or long-term effect on surrounding geology or soils. Long-term indirect effects, primarily from vehicle traffic for operational support and maintenance, would result in very minor soil compaction and dust generation on gravel access roads and pads.

### 4.1.5.2.5 TPS-X Radar

The TPS-X construction and operation requirements and potential impacts to geology and soils would be similar to that described above for the IDT. The alternative location is the same as the potential IDT site south of the Loran-C Station, and the potential impacts would be similar.

### 4.1.5.3 Alternative 2

#### 4.1.5.3.1 Target

**Construction**

Under Alternative 2, potential adverse effects to site soils from the construction of new target facilities would be similar to that described for Alternative 1 (see section 4.1.5.2.2).

**Operation**

Under Alternative 2, target launch operations would be the same as Alternative 1 and would not result in any direct adverse effects on geology and soils at KLC over the short- or long-term.
4.1.5.3.2 Sensors

Construction

Under Alternative 2, potential adverse effects to site soils from the construction of new sensor facilities would be identical to that described for Alternative 1 (see section 4.1.5.2.4).

Operation

Under Alternative 2, sensor operations would be the same as Alternative 1 and would not result in any direct adverse effect on geology or soils at KLC over the short- or long-term.

4.1.5.4 Alternative 3

Alternative 3 would include all aspects of Alternatives 1 and 2. Because Alternative 1 includes GBIs, targets, and all associated facilities, the construction and flight impacts for Alternative 3 would be as described for Alternative 1.

4.1.5.5 Cumulative Impacts

The KLC EA indicated no significant impact to geology and soils from nine annual launches (Federal Aviation Administration, 1996). It is not likely that the Proposed Action of up to five launches (GBI and/or target) in conjunction with other currently planned or anticipated launches at KLC would exceed nine launches per year, the level of activity analyzed in the KLC EA. Missile launches are discrete short-term events. Sampling programs performed during each launch have not shown any accumulation of missile launch exhaust products and therefore, no substantial impacts are anticipated at KLC. Future operations and improvements at KLC would be similar in scope to those described in prior EAs, with the proposed five launches per year being a part of the planned launches at KLC. Minor alteration of soil chemistry and accumulation of contaminants could occur from the exhaust emissions of multiple missile launches at KLC, but such adverse effects would be highly localized and would not pose a hazard to human health. No long-term cumulative impacts are expected from construction and operation at KLC.

4.1.5.6 Mitigation Measures

No specific mitigation measures are proposed. Standard measures for seismic safety would include provision for proper anchoring and/or dampening of missile components and fuel canisters while in storage. Likewise, missile storage buildings and Missile Assembly Buildings would be inspected to ensure structural integrity of foundation, roof, wall connections, and storage racks would be inspected to reduce risk to program personnel during a design seismic event. Before determining the final site layout and design standards for ETR facilities, information bearing on seismic design and construction standards and surface faulting potential would be considered by the design engineer and geotechnical consultant.
4.1.6  HAZARDOUS MATERIALS AND HAZARDOUS WASTE—KODIAK LAUNCH COMPLEX

Potential impacts from hazardous materials would involve their transportation, storage and use. Potential impact from hazardous waste would be related to the generation, accumulation, transportation, and disposal of hazardous wastes used or created in program activities. Impacts relative to hazardous materials and waste are considered significant if they would: (1) increase the potential for exposure to hazardous material or waste; (2) increase the likelihood of a release to the environment; (3) result in noncompliance with applicable regulatory guidelines; or (4) increase the quantities of hazardous materials used or wastes generated beyond available management practices.

Transportation, storage, and use of hazardous materials would be conducted according to applicable OSHA, EPA, DOT, DoD and state regulations and requirements as well as established project and launch complex Standard Safety Operating Plans.

Pollution prevention, recycling, waste minimization, IRPs, USTs, ASTs, asbestos, lead-based paint and PCBs have been evaluated and no impacts were identified. Potential impacts from launch activities are addressed under each alternative as applicable.

4.1.6.1  No Action Alternative

Missile Defense Agency

Under the No Action Alternative, KLC would continue to operate as a commercial launch facility and provide ongoing support to single Strategic Target System launches. The Strategic Target System launches would be managed within the nine launches previously analyzed in the KLC EA (Federal Aviation Administration, 1996), and no hazardous materials or hazardous wastes impacts would be anticipated.

Federal Aviation Administration

There would be no impacts expected from hazardous materials and hazardous waste from the FAA’s No Action Alternative because there would be no launch events from KLC.

4.1.6.2  Alternative 1

4.1.6.2.1  Ground-Based Interceptors

Construction

Construction activities in support of GBI launch activities at KLC are generally discussed in section 2.3.1.1 and include GBI silo or launch pad and support facility construction as well as the IDT, COMSATCOM, TPS-X radar, mobile telemetry and C-band radar gravel pad construction; maintenance storage building and Launch Control Complex additions; addition to the existing Narrow Cape Lodge; construction of a new mancamp; and utilities/communication installation. Construction activities would be centralized to the greatest extent possible at the selected project site and on specific construction laydown areas and access roads. Hazardous materials and waste management would be performed in accordance with ongoing KLC procedures, as described in the KLC User’s Manual (Alaska Aerospace Development Corporation, 2001) as well as applicable federal, state and local regulations.
The construction of the GBI launch support infrastructure would use small quantities of hazardous materials, which would result in the generation of some hazardous and nonhazardous wastes (Halliburton NUS Environmental Corporation, 1993). The hazardous materials that are expected to be used are common to construction activities and may include diesel fuel, anti-freeze, hydraulic fluid, lubricating oils, welding gases, and small amounts of paints, thinners, and adhesives.

Substantial impacts to the environment are not expected from the presence of potentially hazardous materials and the generation of wastes during the GBI construction activities. Best practices, lessons learned and expectations indicated in the interim guidance DoD 5000.2R would be incorporated into design and construction plans. The following hazardous materials management techniques may be used during the construction period to minimize (1) the amount of hazardous materials stored, (2) the threat of their accidental and unplanned release into the environment, and (3) the quantity of hazardous waste generated.

- Structures may be prefabricated by manufacturers and shipped for final assembly at the site using bolts to minimize the need for welding, painting, and other activities involving hazardous materials.
- No underground tanks exist at KLC and none would be installed as a result of this activity. Diesel fuel would be stored in ASTs with secondary containment and inspected daily in accordance with the provisions of the KLC SPCC Plan (as appropriate). ASTs may be removed after tests are complete or put in standby condition at KLC to support future activities. Fueling would follow existing procedures to minimize the potential for fuel spills.
- Bulk hazardous materials [e.g., 210-liter (55-gallon) drums of anti-freeze, hydraulic fluid, compressed welding gases] would be stored in approved containers that meet National Fire Protection Association industrial fire protection codes and required containment systems.
- Spill response materials (e.g., sorbents, drain covers, mops, brooms, shovels, drum repair materials and tools, warning signs and tapes, and personal protective equipment) would be readily available for use in the event of an unplanned release.
- Storage of hazardous materials would be in protected and controlled areas designed to comply with site-specific SPCC plans.
- Hazardous materials would be inspected before accepting a shipment (e.g., to validate container integrity, expiration date, etc.).
- Hazardous materials would be purchased in appropriately sized containers (e.g., if the material is used by the can, it would be purchased by the can rather than in bulk-sized containers).
- Over-purchasing of hazardous materials would be avoided.
- Hazardous material containers would be appropriately labeled.
- At the completion of the construction period, unused amounts of hazardous materials would be the responsibility of the construction contractors and would be safely removed from the site.

Nonhazardous and hazardous waste generated during construction activities include construction debris, empty containers, spent solvents, waste oil and anti-freeze, spill cleanup
materials (if necessary), and lead-acid batteries from construction equipment. Hazardous waste would be containerized and properly disposed of by individual contractors in accordance with Alaska Administrative Code, Title 18 - Environmental Conservation, Chapter 16 and KLC requirements. No permitted hazardous waste treatment or disposal facilities exist on Kodiak Island; therefore, all hazardous waste would be transferred by licensed hazardous waste transporters to the mainland for appropriate treatment or disposal.

The volume of nonhazardous, construction generated waste is expected to be small based on past experience. Nonhazardous waste would be removed by individual contractors for appropriate disposal at the Kodiak Island Borough landfill or at a landfill on the Alaska mainland. The construction schedule for the facility is approximately 15 months, with approximately 100 individuals involved in the construction process. Buildings may be constructed of prefabricated metal resulting in relatively small volumes of non-recyclable construction waste. Debris resulting from site preparation such as tree stumps would be burned onsite, and soil excavated during construction activities would be stockpiled for later onsite use.

**Operation**

*Pre-Launch Activities*

Missile components would be transported to KLC for temporary storage, pre-launch assembly and checkout, and launch preparation. Like the target missiles, the GBI components would be shipped to KLC as finished products that required only final assembly onsite. The hazardous materials contained within the missiles include solid fuel for the rocket and fuel and oxidizer for the EKV’s Divert and Attitude Control System propellant system. No separate fueling would occur; therefore, the likelihood of release and environmental effect would be small.

The handling and use of hazardous and toxic materials at the launch site during and between launch operations would be limited. Potentially hazardous materials used for maintenance, grounds keeping, and housekeeping activities would normally consist of fuel (external to those preloaded into the missiles) required for emergency power and heat, various solvents and cleaners, paints and primers, adhesives, and lubricants. It is expected that no more than 4 liters (1 gallon) of each of the solvents, cleaners, paints, adhesives, and lubricants would be present at any one time (U.S. Department of the Air Force, 1994b), with no more than 38 liters (10 gallons) in total. Fuel for the emergency generators would be stored in dedicated ASTs with secondary containment. The ASTs would be routinely inspected. The hazardous material and waste management techniques described for construction would also be followed during pre-launch operations. Again, substantial impacts to the environment are not expected from the use of potentially hazardous materials and generation of wastes during launch operations.

*Launch Activities*

GBI launch activity considerations include the Launch Hazard Area, flight corridor clearance, missile launch, and missile impact.

Emergency response would be required in the event of a pre-launch or post-launch event which resulted in the partial destruction of a missile. Such an event could result in the rupture of a rocket engine and exposure of the solid fuel. In the event of such mishap, spillage of the propellants could occur. The incident would be handled as an explosive ordnance event, and remaining potentially hazardous materials would be regarded as hazardous waste for
management purposes. Removal and disposal of nonhazardous and hazardous waste from KLC would be in accordance with applicable state and federal requirements.

One piece of equipment used on the EKV consists of a klystron tube which contains small quantities of beryllium. Beryllium is listed on the Toxic Substance Control Act Inventory. If maintenance were required, a new tube would be brought onsite and the replaced tube would be returned to the manufacturer for repair.

Post-Launch Activities
Following test activities, the GBI facilities would be readied for the next use or placed in standby mode. Post-launch activities would generally occur as discussed under the No Action Alternative target launch operations.

4.1.6.2.2 Targets

Construction
Construction activities would include target access roads, target launch pad, Movable Missile Building, Missile Assembly Building, Motor Storage Building and access road, existing Narrow Cape Lodge expansion, new mancamp construction, and utilities/communications installation. Generation of potential hazardous waste (e.g., corrosion control coatings, adhesives, and sealants) would be minimal. Management of hazardous materials and hazardous waste would be performed in accordance with AADC requirements, and would not significantly impact existing KLC hazardous materials and hazardous waste management procedures.

Operation

Pre-Launch Activities
Potential target missiles are described in section 2.1.2. Pre-launch activities include transportation of target missiles to KLC, temporary storage, pre-launch assembly and checkout and preparation of the missiles for launch. Missiles would be transported to KLC as ready-to-use components and assembled onsite. The launch operator would be responsible for transporting the fuel in accordance with DOT requirements. Because of the sealed nature of this mode of transport, the likelihood of release and environmental effect is small. No separate fuel transportation, onsite storage, or fueling operations would be performed.

The handling and use of potentially hazardous materials at the launch site during and between launch operations would be limited. Hazardous materials used for maintenance, grounds keeping, and housekeeping activities would normally consist of various solvents and cleaners, paints and primers, adhesives, and lubricants. It is expected that no more than 4 liters (1 gallon) of each of these types of materials would be present at any one time (U.S. Department of the Air Force, 1994b), with no more than 38 liters (10 gallons) in total.

Onsite waste management practices would include:

- The containerization of waste to prevent discharges of waste or leachate
- The prevention of litter
- Controlling access by wildlife or disease vectors
- Keeping the premises free of solid waste
- The use of best available management practices for the control and prevention of runoff and erosion

*Launch Activities*

During a normal launch there would be minimal to no hazardous materials or hazardous waste impacts. However, safety procedures would be followed.

Potentially hazardous substances such as hydrogen chloride, aluminum oxide, carbon monoxide, and oxides of nitrogen would be generated from combustion of the solid rocket propellant during launch or in the event of a launch failure or abort. For a nominal launch, propellant would burn to completion. Although unlikely, it is possible that a rocket’s flight could be terminated early. In the event of an on-pad or in-flight launch failure, solid propellant could be expected to scatter over a wide area. The missile debris would impact inside the Launch Hazard Area. In such an impact, the rocket would contain a varying level of propellant that would depend on the flight time. If scattered on the ground, potential pollutant concentrations downwind are expected to be less than with a normal launch, as the solid propellant would burn more slowly in the open air than in a rocket motor. There would be minimal to no impact to mission critical personnel or to the public from such an incident.

There is also the unlikely possibility that an errant missile could impact off target. Should an off-target impact occur, the Range Safety Manager would be notified immediately. The Range Safety Manager would in turn report the incident to the appropriate public officials and initiate appropriate emergency response actions. Emergency response actions would be in accordance with the KLC User’s Manual.

*Post-Launch Activities*

Small amounts of potentially hazardous and nonhazardous wastes are expected to be generated during launch operations. Wastes would be segregated as nonhazardous, hazardous, and possibly special wastes for collection and disposal.

Nonhazardous waste would be removed for appropriate disposal at the Kodiak Island Borough landfill or on the Alaska mainland. Removal and disposal of nonhazardous and hazardous waste from KLC would be done in accordance with applicable state and federal requirements.

Hazardous materials management would be performed in accordance with ongoing KLC procedures, as described in the KLC User’s Manual (Alaska Aerospace Development Corporation, 2001) and the Alaska Hazardous Waste Management Regulations (Alaska Administrative Code, Title 18, *Environmental Conservation*, Chapter 16). Hazardous waste management at KLC would be the responsibility of the generator. Hazardous wastes would be collected for disposal in accordance with applicable federal, State of Alaska, and DoD requirements.
Since no permitted hazardous waste treatment or disposal facilities exist on Kodiak Island, all hazardous waste would be shipped to the mainland for appropriate treatment or disposal. Only licensed hazardous waste transporters would be used to transport hazardous wastes off site.

Post-launch activities would involve the release of Launch Hazard Areas, cleanup, and transportation from KLC. Following test activities, the launch facilities would be readied for the next use or placed in standby mode. Specific restoration actions would be determined on a case-by-case basis in coordination with the procedures of KLC and the Alaska Department of Environmental Conservation.

4.1.6.2.3 In-Flight Interceptor Communications Data Terminal

Construction
Alternative 1 would require the construction of one IDT (among three alternative sites), one COMSATCOM (among four alternatives), and connecting roads. Construction would include a gravel pad, concrete pad, security fencing and utilities/communications installation. Generation of potential hazardous waste (e.g., corrosion control coatings, adhesives, and sealants) would be minimal. Management of hazardous materials and hazardous waste would be performed in accordance with AADC requirements, and would not significantly impact existing KLC hazardous materials and hazardous waste management procedures.

Operation
Operation of the IDT and COMSATCOMs would have little effect on hazardous waste and hazardous materials management. A 3,785-liter (1,000-gallon) AST would be used for diesel fuel for the backup generator.

4.1.6.2.4 Sensors

Construction
Alternative 1 would require several gravel pad areas out of seven alternate locations for mobile telemetry. An existing disturbed area would be utilized, and therefore potential impacts related to hazardous materials and hazardous waste would be minimal.

Operation
Operation of the sensors would have minimal direct or indirect, short- or long-term effect on hazardous materials and hazardous waste.

4.1.6.2.5 TPS-X Radar

The TPS-X construction and operation requirements and potential impacts to hazardous materials and hazardous waste management would be similar to that described above for the IDT. The location would be the same as those described for the potential IDT and COMSAT facilities, and the potential impacts would be similar.
4.1.6.3 Alternative 2

Alternative 2 is similar to Alternative 1, except that GBI and IDT construction and operation activities would not occur and sensor operation would support only target missile launches.

4.1.6.4 Alternative 3

Because Alternative 1 includes GBIs, targets, and all associated facilities, the construction and operation impacts for Alternative 3 would be as described for Alternative 1.

4.1.6.5 Cumulative Impacts

Adherence to the existing hazardous materials and waste management systems on KLC would preclude the potential accumulation of hazardous materials or waste. The range has implemented an emergency response procedure that would aid in the evaluation and cleanup of any potentially hazardous materials released. The types of hazardous materials used and waste generated would be similar to those currently used at KLC. It is not likely that the Proposed Action of up to five launches (GBI and/or target) in conjunction with other currently planned or anticipated launches at KLC would exceed nine launches per year, the level of activity analyzed in the KLC EA. The proposed launch of GBI or target missiles is not expected to substantially increase the volume of hazardous materials used, or hazardous waste generated, at KLC. Therefore, proposed activities would not be expected to result in cumulative hazardous materials and hazardous waste impacts.

4.1.6.6 Mitigation Measures

No hazardous materials/hazardous waste mitigation measures are proposed for the GMD ETR activities at KLC.

4.1.7 HEALTH AND SAFETY—KODIAK LAUNCH COMPLEX

Missile launches by their very nature involve some degree of risk and it is for this reason that DoD and AADC has specific launch and range safety policies and procedures to assure that any potential risk to the public and government assets (launch support facilities) are minimized. Potential issues related to health and safety would include the transportation of missile components, the reliability of components during handling/assembly and launch associated debris and emissions. Appendix B includes a detailed discussion of safety policies and regulations. Appendix C contains a discussion of flight test safety.

4.1.7.1 No Action Alternative

Missile Defense Agency

Under the No Action Alternative, KLC would continue to operate as a commercial launch facility and provide ongoing support to single Strategic Target System launches. The Strategic Target System launches would be managed within the nine launches previously analyzed in the KLC EA (Federal Aviation Administration, 1996). Potential health and safety risks from debris impact, toxic chemical dispersion (exhaust emissions), and noise would be associated with pre-launch, launch, and post-launch activities. Planning and execution of target launches would be in compliance with federal, state, and local health and safety requirements and regulations, as
well as DoD and KLC Safety Policy. Adherence to such requirements ensures that potential risk to
the general public, workers, and the launch areas do not exceed acceptable limits. Therefore, no increase in potential risk to health and safety would be expected as a result of selecting this alternative.

Federal Aviation Administration
There would be no impacts expected to health and safety from the FAA’s No Action Alternative because there would be no launch events from KLC.

4.1.7.2 Alternative 1

4.1.7.2.1 Ground-Based Interceptors

Construction
Construction activities in support of GBI launch activities at KLC are generally discussed in
section 2.3.1.1 and include GBI silo or launch pad and support facility construction as well as the IDT, COMSATCOM, TPS-X radar, mobile telemetry, and C-band radar gravel pad
construction, maintenance storage building and Launch Control Complex additions, addition to
the existing Narrow Cape Lodge, construction of a new mancamp and utilities/communication
installation. Construction activities would be centralized to the greatest extent possible at the
selected project site and on specific construction laydown areas and access roads. All new
construction or structure modification would be accomplished using the same procedures that
AADC used to construct the present KLC infrastructure.

Public access would be restricted in accordance with the KLC’s Interagency Land Management
Agreement that encourages public access except in cases where safety is concerned or
protection of structures is needed. A health and safety plan would be prepared by the contractor
and submitted to KLC/AADC to ensure the health and safety of onsite workers. A formally trained
individual would be appointed to act as safety officer. The appointed individual would be the point
of contact on all problems involving job site safety. During performance of work, the contractor
must comply with all provisions and procedures prescribed for the control and safety of
construction team personnel and visitors to the job site. Compliance with regulations would
ensure that construction or modification of facilities would not impact health and safety of workers
or range personnel. No impact to public health and safety would be expected.

Operation

Pre-Launch Activities
Pre-launch activities would include transportation of boosters, liquid fuel, and liquid oxidizer
tanks for the EKV and missile preparation, assembly, and integration testing. Missile
components and support equipment would be transported to Kodiak Island by sea or air from
Government storage depots or contractor facilities. The interceptor may arrive at Kodiak with
the EKV attached or the booster may be shipped separately from the EKV. All components and
equipment would be handled and shipped in accordance with applicable military, state, and
DOT regulations. Missile components would be packaged in shipping containers designed
according to Alaska, DOT, and military requirements for protection of missile components and
reduction of fire/explosion or risk of hazardous materials release in the event of an accident. All
containers would have proper placards.
Sections 3.1.11 and 4.1.11 provide detailed discussion on Kodiak Island and KLC established air, ocean, and ground transportation systems. The primary hazard related to the transportation of missile components would be the potential for an accident involving the transport vehicle and a resulting explosion/fire of solid fuel motors and/or small explosive actuation devices (used in missile control and Flight Termination System). Operations involving the transport of explosives (including packaging and handling for movement) would require implementation of written procedures, which would be approved by KLC/AADC. Transport operations would be conducted under the supervision of an approved ordnance officer using explosive-certified personnel as necessary. Consequently, minimal health and safety impacts would be expected during transport of missile components.

Missile components transported by barge to the Port of Kodiak would likely arrive at the Lash Terminal. Lash is a privately owned terminal operated and serviced by Seaport Terminal Services, Inc. The Lash Terminal is licensed for explosive and hazardous materials handling. Lash is located south of the U.S. Coast Guard Station on the main road to KLC. Samson Tug & Barge routinely serves the Port of Kodiak from Seattle and Anchorage, and is familiar with aerospace transport requirements. A sealift accident during transport is considered highly unlikely. The potential for a major accident (sinking or total destruction of the seacraft) is minimal.

Once unloaded at Kodiak Island, missile components and support equipment could be shipped by tractor-trailer transport to KLC or barged to one of the following potential beach landing areas, Burton Ranch Beach (mancamp location), Boulder Beach (near Bear Paw Ranch), and Pasagshak Beach (near the Pasagshak Recreation Area). The Narrow Cape Lodge is an example of direct barge delivery to KLC. Temporary beach closure would be necessary, but would be considered routine and of short duration.

In each of the described cases, the accident probability presented reflects only the potential for an accident involving the transport vehicle. Only a small fraction of such accidents would affect missile propellants or explosives being transported due to the use of specialized shipping containers that protect the shipment. Consequently, minimal health and safety impacts would be expected during transport of missile components.

Appropriate safety measures as established by AADC would be instituted at the receiving terminals or airport. These safety measures include specified receiving and parking areas (for transport vehicles), establishment and enforcement of applicable ESQDs around receiving areas, restricting handling and transportation of missile components to specific and properly trained personnel, and using established and permitted transportation routes from the receiving terminal or airport to KLC.

Use of the Kodiak State Airport shared by commercial pilots and the U.S. Coast Guard would be required to support receipt and transportation of missile components and mission personnel (figure 4.1.7-1), just as has been done for previous rocket motor shipments to KLC. The ESQD would be 434 meters (1,425 feet) to any inhabited buildings and 260 meters (855 feet) to public traffic routes. A designated preferred parking/offloading area has been established at Kodiak Airport that would limit impact to the Buskin River State Recreation Site. An alternative parking/offloading area would be the location used during previous U.S. Air Force missile launches. In the event this alternate location is required, the ESQD would encroach on several campsites within Buskin River State Recreation Site and could require closure of the recreation site for one night while the boosters are at the airport. AADC would provide a 30-day advance

GMD ETR Final EIS

4-57
notice to Alaska State Parks regarding the closure. Once the boosters have been removed from the area, the ESQD would no longer be in effect and the campsites would again be accessible.

There would be no effect on U.S. Coast Guard Air Station search and rescue operations. Handling and transportation of the missile components would stop, or move, to allow the Coast Guard to proceed in the event of a search and rescue operation, and would resume after the all clear is provided.

For analysis purposes, a quantity of 20,410 kilograms (45,000 pounds) of division 1.1 explosive was assumed. An inhabited building ESQD with a radius of 434 meters (1,425 feet) would be established. The public transportation route ESQD would be 261 meters (855 feet). If the propellant is determined to be Division 1.3 explosive (22,700 kilograms [50,000 pounds]) then the ESQDs would be reduced to 74.7 meters (245 feet) for inhabited buildings and 74.7 meters (245 feet) from public transportation routes. The ESQD is based on information provided in Inhabited Building and Public Traffic Route Distances, DoD 6055.9-STD, Ammunition and Explosives Safety Standards. The ESQD determination would be based on the equivalent explosive force of all propellant and pyrotechnic materials contained in the flight vehicle. Establishment of the ESQD zone represents DoD’s determination that areas outside the zone provide acceptable protection, and requires that areas inside the ESQD zone be cleared of non-mission-essential personnel for the entire period during which the explosives are present. The ESQD would keep unauthorized personnel and individuals at a safe distance until the boosters are unloaded and transported by truck to KLC. The transportation route would be in accordance with the permit application submitted to and approved by the State of Alaska Department of Transportation before shipment of missile components. Transport of missile components is not expected to be a hazard to private properties along the transportation route. The same ESQDs would be established and enforced while the missile components are at KLC.

Access to launch support structures and hazardous materials storage areas would be limited to KLC/mission essential personnel. All personnel associated with the Proposed Action would be properly trained in compliance with applicable health and safety procedures and guidelines. All pre-flight hazardous operations would be conducted in accordance with applicable and routine safety regulations and operations plans.

The solid propellant used in the GBI missiles is very stable in the absence of an ignition source. The boosters would be grounded to help protect against lightning and static electricity. Electrostatic discharge ignition of boosters has been associated with low atmospheric moisture levels. Based on the high-moisture atmospheric conditions in Kodiak, it is unlikely that an electrostatic discharge would occur. To prevent a premature activation of the igniters or the Flight Termination System, the boosters would not be armed until just before launch.

The boosters would be processed and prepared for launch in the same manner as previous and ongoing missile launches from KLC. The major system components (boosters, in-flight destruct package, range safety equipment, and missile instrumentation) would be assembled and tested in the Integration and Processing Facility. All preparation activities would be conducted in accordance with applicable safety regulations and operations plans.
The handling and assembly of missile components, accomplished within enclosed buildings, has the potential to affect worker health and safety. RCC Standard 321-02 limits those collective risks to $1 \times 10^{-3}$ for non-mission essential personnel and to $1 \times 10^{-2}$ for mission essential personnel. Due to design of the buildings and implementation of ESQDs, the health and safety of the general public would not be affected. Assembly of missiles is considered routine at KLC. Adherence to appropriate safety regulations and operating plans would serve to maintain health risks to mission personnel within the RCC acceptable levels.

Each GBI missile would have an EKV assumed to contain approximately 7.5 liters (2.0 gallons) of liquid fuel and 5.5 liters (1.5 gallons) of liquid oxidizer (variations of monomethyl hydrazine and nitrogen tetroxide). The transportation of the EKV tanks containing liquid fuels and oxidizers would be conducted in accordance with state and federal regulations (49 CFR 106-180, University of Alaska, Fairbanks [UAF] Policy 902, Bureau of Explosives Tariff No. BOE 6000-1). The tanks would protect against releases in the unlikely event of a transportation accident and therefore would meet DOT requirements. The EKV would have proper placards and only military or commercial carriers licensed to handle or transport hazardous materials would be utilized.

There is the potential of ignition in an accident because the liquid propellants are sensitive to heat. However, the DoD has considerable experience with shipment of missiles and sensitive missile components, including liquid propellants.

On arrival at KLC, the pre-loaded EKV fuel tanks would be stored in the Integration and Processing Facility or would be placed in the existing hypergolic fuel storage building and/or the proposed oxidizer storage building until needed for installation on the EKV. The facility would use appropriate placards, and access would be limited to KLC and authorized mission personnel. All personnel associated with the handling of the tanks and installation on the EKV would be properly trained in compliance with UAF 601 and 29 CFR 1910 procedures and guidelines. Safety zones and personal protective equipment would be available based on the U.S. Air Force Toxic Dispersion Model spill model. Copies of MSDSs would be available. The facility would have fire protection equipment and would be inspected and maintained according to IFC 2000, 40 CFR 264, NSS 1740.12, UAF Document 601 and other applicable standards.

There is the potential of spill or release from damaged or leaking tanks; however, minimal health and safety impacts would be expected due to the small quantity of liquid propellant as well as storage and containment protocol and worker training.

**Launch Activities**

Before each launch at KLC, the Range Integrator and the Missile Flight Safety Officer must approve all flight plans and trajectories and planned impact areas. The Missile Flight Safety Officer would issue range clearance and surveillance for the following designated areas: safety exclusion zone, Launch Hazard Area, flight termination lines and flight safety corridor (figure 4.1.7-2).

**Safety Exclusion Zone.** The duration and size of the actual exclusion zone would be defined for each test and would vary depending on the missile size, altitude and direction and meteorological conditions (wind velocities) at the time of launch.
**EXPLANATION**

**Figure 4.1.7-2**

**Kodiak Launch Complex, Alaska**

**GMD ETR Final EIS**
Launch Hazard Area. A launch-site malfunction would potentially result in the scattering of the resulting missile debris anywhere within the Launch Hazard Area. The Launch Hazard Area includes those areas within and adjacent to the site within and up to a 2,743-meter (9,000-foot) radius of the launch pad. The public would be excluded well outside the Launch Hazard Area shown (figure 4.1.7-2).

Flight Termination Line. The flight termination line defines the limit/boundary at which flight termination would be initiated in order to contain the vehicle and its fragments within predetermined hazard and warning areas, such that the risk to personnel and non-mission aircraft and ships is within the RCC Standard 321-02 limits of $1 \times 10^{-7}$, $1 \times 10^{-7}$ and $1 \times 10^{-6}$, respectively. Warning areas are regions along the vehicle flight corridor where a possible hazard to aircraft and sea vessels exists because of missile flight operations. Figure 4.1.7-2 shows a flight termination line, including the representative exclusion and warning areas.

Failure of a missile guidance system that would cause debris to fall outside the termination line would be detected by the Range Safety Officer, who would terminate the missile flight before it could cross the flight hazard area. The range safety program includes redundant airborne command destruct systems that would permit in-flight tracking of the test missile. Remote area safety aircraft would be used for real-time monitoring of missile performance and evaluation of flight termination criteria. The termination system provides a mechanism by which impact lines would not be violated in the unlikely event of a malfunction during flight. Therefore, potential impacts to health and safety would not be significant.

Flight Safety Corridor. A probabilistic risk analysis would be performed before each flight test to determine that the individual risk to the general public is less than the RCC Standard 321-02 criteria of $1 \times 10^{-7}$ per launch. The probabilistic risk assessment would also predict the risk to all areas near the vehicle ground track, both inside and outside the Launch Hazard Area. Debris from booster drops, an in-flight malfunction and termination would potentially impact within the flight corridor footprint shown in figure 4.1.7-3. Additionally, regions within and beyond U.S. territorial waters where the hazard exceeds the limits stipulated in RCC Standard 321-02 (the warning area around KLC and the area along the missile trajectory) would be verified clear of ships and aircraft before launch. KLC would coordinate launch operations with the FAA, U.S. Coast Guard, and the Alaska Department of Fish and Game and issue NOTAMs and NOTMARs before launches.

The proposed launches at KLC would utilize launch azimuths between 125 and 225 degrees. Figure 4.1.7-3 indicates the major inhabited area near the westernmost (225 degree) launch profiles would be Old Harbor. Nominal flight profile data indicates that debris from launches would not reach this area. This risk would be evaluated on a launch-specific basis for each mission and events would be controlled so that the risk would remain below $1 \times 10^{-6}$. Launch azimuths of 125 to 225 degrees were previously analyzed in the KLC EA (Federal Aviation Administration, 1996). This document concluded that KLC takes every reasonable precaution during the planning and execution of these launch operations to prevent injury to human life or property, and no increased risk to health and safety is expected as a result of implementing this alternative.
Old Harbor
Flight Safety Corridor
Through Forty
Seconds of Flight on
Flight Corridor 225 Degrees

Kodiak Island, Alaska

Figure 4.1.7-3

The Range Safety Officer would establish the safety zones around the launch site and along the missile flight path no less than 4 hours before each launch. This area would be cleared of non-mission participating aircraft and ships by establishing warning and restricted areas, publishing NOTMARs and NOTAMs and by maintaining close liaison and coordination with agencies controlling both air and surface traffic. The Range Safety Officer would then ensure the safety exclusion zone is verified clear of non-mission essential personnel and vessels out to the territorial limit approximately 20 minutes before launch.

The area of Kodiak Borough in the vicinity of KLC is sparsely populated. The flight corridor, including the booster drop zone, would be mostly over open water. Therefore, proposed flight activities would pose minimal threat to the general public. Personnel inside the safety exclusion zone would be limited to mission essential personnel. Mission essential personnel (specifically those required to be within the evacuation area to conduct the launch) would remain within facilities, such as the Launch Control and Management Center, rated to provide adequate blast and debris protection and to which positive communications would be maintained at all times.

Flight testing evacuations, clearances, and road closures are expressly intended to ensure both worker and public health and safety. Evacuation includes conducting appropriate ground, open ocean, and air surveillance sweeps to ensure that all areas are evacuated.

The implementation of AADC’s safety programs and practices at KLC before and during launch activities would limit the number of personnel exposed to increased hazards and, as a result, no significant health and safety impacts are expected.

The potential effect of launch emissions and noise are discussed in sections 4.1.1 and 4.1.9 respectively.

Post-Launch Activities
Safety exclusion zones would be released or cleared for re-entering when the Missile Flight Safety Officer is assured that missile flight tests are completed and any residual gases, debris, or similar hazardous concerns are no longer a potential threat to worker or public health and safety. Debris would primarily consist of metal fragments. Much of any hazardous material in the missile would be consumed in the case of launch anomaly. If necessary, debris recovery activities would be conducted in accordance with DoD regulations and KLC safety plans and procedures and would not be expected to effect public health and safety.

Any potentially hazardous concerns remaining after a flight or flight termination would be handled in accordance with the KLC Safety Policy and Explosive Ordnance Disposal Plan. Disposal activities would be in accordance with KLC Explosive Ordnance Disposal Plan, NPD 600.1 Transportation Management Guidelines and applicable state and federal regulations. Implementation of these regulations and procedures would to prevent risks to the general public, KLC and program personnel.

Any necessary launch site restoration and maintenance operations would also be considered routine activities on KLC. Restoration and maintenance activities at the proposed launch sites would not have a significant impact on health and safety at KLC.
4.1.7.2.2 Target

Construction

Construction of several new facilities would occur as described in section 2.3.1.1. All construction and structure/infrastructure modification would be accomplished in accordance with the safety plans and procedures and regulations as described in section 4.1.7.2.1.

Operation

Pre-Launch Activities

Pre-launch activities include the transportation and assembly of the target at KLC. The fourth stage of a Peacekeeper target would utilize a single liquid propellant (hydrazine), and onsite loading would be required. A safety briefing would be held prior to loading and hazardous operations checklist would be completed. All persons performing the loading would wear personal protective suits and all non-essential personnel would leave the loading area. Approximately 236 kilograms (520 pounds) of hydrazine would be transferred at a rate of approximately 5.4 kilograms (12 pounds) per minute during fuel loading operations.

If an accidental release were to occur, it would most likely occur during loading. A reasonable scenario would involve failure of the transfer equipment or valves. Any small leaks/spills would be contained in a drip pan partially filled with water. Water would be added to larger leaks/spills to dilute the hydrazine and moist absorbent pads/booms would be used to contain and isolate the release. As discussed in section 4.1.1.2.2, analysis assumes a leak contained over a 3-minute period that releases up to 17 liters (4.5 gallons) of hydrazine fuel. Analysis indicated no potential exceedances of the IDLH health standard of 50 ppm. The low likelihood of such an occurrence and the implementation of approved emergency response plans would limit the impact of such a release. No impact to the general public would be expected.

Launch Activities

Proposed target launches would be similar to previous target launches at KLC. These land launched target missiles could consist of one of several types of missiles including Strategic Target System, Minuteman II Target, Peacekeeper Target, and Trident I (C4) Target. Table 4.1.1-12 lists missile propellant information, and table 4.1.1-13 lists potential emission constituents during Stage I for each proposed missile. A total of five missile launches (GBI and/or target) per year would be anticipated at KLC over the duration of the program.

As described under section 4.1.7.2.1, Operations, Launch Activities, before each launch at KLC, the Range Integrator and the Missile Flight Safety Officer must approve all flight plans and trajectories and planned impact areas. The Missile Flight Safety Officer would issue range clearance and surveillance for the following designated areas: safety exclusion zone, Launch Hazard Area, flight termination lines and flight safety corridor (figure 4.1.7-2).

Safety Exclusion Zone. The duration and size of the actual exclusion zone would be defined for each test and would vary depending on the missile size, altitude and direction and meteorological conditions (wind velocities) at the time of launch.

Launch Hazard Area. A launch-site malfunction would potentially result in the scattering of the resulting missile debris anywhere within the Launch Hazard Area. The Launch Hazard Area
includes those areas within and adjacent to the site within and up to a 2,743-meter (9,000-foot) radius of the launch pad. The public would be excluded well outside the Launch Hazard Area shown (figure 4.1.7-2). In defining the launch hazard area for a dual Peacekeeper launch, air quality modeling would be conducted to allow consideration of potential air quality impacts from a launch pad accident.

**Flight Termination Line.** The flight termination line would be as discussed for a GBI launch in section 4.1.7.2.1.

**Flight Safety Corridor.** The flight safety corridor would be as discussed for a GBI launch in section 4.1.7.2.1.

**Post-Launch Activities**

Post-launch activities would be as described for the GBI in section 4.1.7.2.1.

**4.1.7.2.3 In-Flight Interceptor Communication System Data Terminal**

Implementation of Alternative 1 would include modification of existing support facilities and structures to increase current communications capability.

**Construction**

Alternative 1 would require the construction of one IDT (among three alternative sites), one COMSATCOM (among four alternatives), and connecting roads. Construction activities would be accomplished in accordance with the safety plans and procedures described in section 4.1.7.2. No adverse effects to health and safety are expected from IDT and COMSATCOM construction.

**Operation**

For communication link equipment, associated RF emissions are considered to be of sufficiently low power so that there would be no exposure hazard. All sensor systems would be sited before operation to ensure that no occupied structures or accessible travel areas would be within any hazard area necessitated by radio frequency emissions. Through the use of these procedures, it has been previously determined that proper exposure control would be achieved, and that operation of these systems would not present a significant health and safety hazard (U.S. Army Space and Strategic Defense Command, 1993b).

Security measures, such as fencing, would prohibit public access to the IDT site and keep the area free from any equipment that could cause electronic interference with the IDT receiving band.

Maintenance of the IDT would require occasional testing of the diesel powered electrical generators and replacement of the Klystron tube, which contains small quantities of beryllium. No hazardous materials or wastes would be generated as a result of generator testing. Potentially hazardous operations such as fueling of the generators would be conducted in compliance with the safety standards of OSHA, AADC’s safety programs and applicable operating procedures. Adherence to these regulations and procedures would minimize the potential for health and safety impacts.
Exposure to beryllium particles, dust, or fumes can cause chronic beryllium disease, a serious lung disease that can be disabling and even fatal. The current OSHA PELs for beryllium allow exposure to 2 \(\mu g/m^3\) of air as an 8-hour time-weighted average; between 5 \(\mu g/m^3\) and 25 \(\mu g/m^3\) exposure for up to 30 minutes at a time; and 25 \(\mu g/m^3\) as a maximum peak limit that can never be exceeded. Handling and replacement of the tube would not likely result in direct exposure of workers to beryllium, since the beryllium would be contained and any necessary repairs to the tube would be done off range by the tube’s manufacturer. Personal protective equipment would be available. Work practices, worker training and engineering controls, such as ventilation, would be used to further reduce the potential of beryllium exposure. No impact to public health and safety from IDT operation and maintenance would be expected.

4.1.7.2.4 Sensors

Construction

Proposed sensor use at one location on KLC and at one out of seven alternate sites throughout south-central or southwest Alaska would require that sensors be transported to these locations. Mobile systems would likely be parked at pre-existing parking areas. No adverse effects to health and safety are expected.

Operation

For communication link equipment, associated radio frequency emissions are considered to be of sufficiently low power so that there is no exposure hazard. All sensor systems would be sited before operation to ensure that no occupied structures or accessible travel areas are within any hazard area necessitated by radio frequency emissions. Through the use of these procedures, it has been previously determined that proper exposure control would be achieved, and that operation of these systems would not present a significant health and safety hazard (U.S. Army Space and Strategic Defense Command, 1993b).

4.1.7.2.5 TPS-X

Construction

The potential TPS-X location would be the same as described for the potential IDT and COMSATCOM facilities site south of the Loran-C station. Construction activities would be accomplished in accordance with the safety plans and procedures described in section 4.1.7.2.1. No adverse effects to health and safety are expected from construction of the TPS-X pad.

Operation

EMR hazard zones would be established within the beam’s tracking space and near emitter equipment. The potential interference distances are shown in figure 2.3.1-8. A visual survey of the area would be conducted to verify that all personnel are outside the hazard zone before startup. Personnel may not enter these hazard zones while the radar is in operation. The radar is prevented from illuminating in a designated cutoff zone, in which operators and all other system elements would be located. Potential safety consequences associated with radar interference with other electronic and emitter units (flight navigation systems, tracking radars, etc.) would also examined before startup. Adherence to AADC, FAA, and DoD safety procedures relative to radar operations would preclude significant impact to health and safety.
4.1.7.3 Alternative 2
Alternative 2 is similar to Alternative 1, except that GBI and IDT construction and operation activities would not occur and sensor operation would support only target missile launches.

4.1.7.4 Alternative 3
Because Alternative 1 includes GBIs, targets, and all associated facilities, the construction and flight impacts for Alternative 3 would be as described for Alternative 1.

4.1.7.5 Cumulative Impacts
There have been six launches as part of various DoD and National Aeronautics and Space Administration programs at KLC. Under these programs, the safety procedures at KLC have developed and matured. The discontinuous launches preclude cumulative health and safety impacts (Department of Energy, 1991c; Strategic Defense Initiative Organization, 1991; U.S. Army Strategic Defense Command, 1991b). The KLC EA indicated no significant impact to health and safety of personnel and the public from nine annual launches (Federal Aviation Administration, 1996). It is not likely that the Proposed Action of up to five launches (GBI and/or target) in conjunction with other currently planned or anticipated launches at KLC would exceed nine launches per year, the level of activity analyzed in the KLC EA. The maximum number of launches that could occur from KLC would be determined by the FAA and would be mandated in the launch site operator license. Safety and health planning would be done at the earliest stages of each missile test program. Implementation of DoD and range safety and health plans and procedures during all phases of operation would avoid or reduce the probability of potential impact to health and safety. Minor impacts from the Proposed Action, when added to other activities in the area, would not likely result in cumulative impacts to public health and safety.

4.1.7.6 Mitigation Measures
No health and safety mitigation measures are proposed for the GMD ETR activities at KLC.

4.1.8 LAND USE—KODIAK LAUNCH COMPLEX
Land use is described as the human use of land resources for various purposes including economic production, natural resources protection, or institutional uses. Land uses are frequently regulated by management plans, policies, ordinances, and regulations that determine the types of uses that are allowable or protect specially designated or environmentally sensitive uses. Potential issues typically stem from encroachment of one land use or activity on another or an incompatibility between adjacent land uses that leads to encroachment. The purpose of the Land Use Resource section is to addresses potential affects of the proposed action upon the use of land and the compatibility of the proposal and its alternatives with respect to the neighboring land uses and activities within an ROI.

4.1.8.1 No Action Alternative
Missile Defense Agency
Under the MDA's No Action Alternative, current operations at KLC with respect to land use would not change. Launches would continue from KLC subject to the terms and conditions of
the FAA’s launch site operator license. KLC’s activities would continue to involve the launching of single target missiles from existing facilities and would not result in any significant impacts to land use. The continuation of launches from KLC would not result in any significant impacts to land use. The AADC will apply for a renewal of their current launch site operator license, which ends in September of 2003. The renewal period would be for another 5 years. This license must be renewed for launch operations to continue at KLC.

The Narrow Cape area is primarily undeveloped and utilized for a number of recreational activities. Since less than 1 percent of Narrow Cape is occupied by KLC and its location is more than 40 kilometers (25 miles) from the Kodiak National Wildlife Refuge, the potential for land use conflicts caused by the existence of KLC is minimized.

Recreational activities along KLC’s coast are available to the public during all times except during a launch or hazardous operations. These short-duration closures of Narrow Cape would not have an appreciable impact on recreation. Under the No Action Alternative, times of non-availability of KLC’s beaches and access to its coastline would continue to be publicized to further minimize the potential for land use conflict.

AADC preserves the coastlines around KLC property in their natural condition. Under the MDA’s No Action Alternative, the continuation of activities at KLC would be compatible with the Alaska CZM Program.

Federal Aviation Administration

Under the FAA’s No Action Alternative, the launch site operator license for KLC would not be renewed and no launches would be allowed to occur from KLC after September 2003. If the FAA’s No Action Alternative is selected, the land at Narrow Cape may become available for other uses. Therefore, no impacts to land use would occur from launches at KLC.

4.1.8.2 Alternative 1

Under the Proposed Action of Alternative 1, several facilities would be constructed as discussed in section 2.3.1.1. Before construction, a Memorandum of Agreement would be required between AADC and MDA regarding construction, operation, and final disposition of MDA facilities on KLC.

4.1.8.2.1 Ground-Based Interceptors

Construction

The construction of two GBI silos or a GBI launch pad and a Mechanical Electrical Building would be confined to and contribute to the development of the ridge site along the northern boundary of KLC. In addition, necessary access roads and an Entry Control building would occur along the corridor yielding access to the northern ridge.

Construction could also add an additional 465 square meters (5,000 square feet) to the existing Launch Control Center and 1,394 square meters (15,000 square feet) to the nearby Maintenance and Storage Building. Modifications and additions would be considered routinely
accomplished operations occurring within a compatible and already existing locale for such use. Likewise, no conflicts with land use would occur within or outside the boundaries of KLC.

Construction of an Oxidizer Storage Building would be located within the vicinity of the existing Hypergolic Storage Building and would not alter the overall land use and management of the surrounding facilities. The siting and use of this area would take into account ESQDs and applicable safety criteria preventing incompatible activities or land use conflicts.

Modifications to the Integration and Processing Facility, to serve as the Missile Assembly Building, would require some interior modifications. Since modifications would be confined within the already utilized Missile Assembly Building, neither changes nor impact to land use would occur. Furthermore, ESQDs and other appropriate safety measures would serve to prevent extending hazards areas.

Necessary housing for additional operation personnel may be provided by a mancamp near the Launch Control Center, or at the Narrow Cape Lodge or nearby hotels. Although the possible construction of a mancamp and additions to the Narrow Cape Lodge would alter the land use, such activity would be compatible with KLC’s Interagency Land Management Agreement between the Alaskan Department of Natural Resources and AADC, which encourages public access except in circumstances where safety or protection of structures are a concern. Furthermore, changes in the use of land would be confined within the immediate project area and only restrict access to a small portion of the total grazing lands.

Maximum use would be made of KLC’s existing infrastructure and facilities. General infrastructure improvements may also be required, such as fencing, road improvements, electrical service, and telephone and data transmission line installation. The decision to accomplish general improvements would be decided as needed, and would be considered minor and routine maintenance activities as described under the No Action Alternative.

A Coastal Project Questionnaire for GMD ETR activities would be submitted to the State of Alaska to confirm that construction activities would be consistent with the Alaskan CZM Program and the Kodiak Island Borough Coastal Management Program. Submission of the Coastal Project Questionnaire would be coordinated among AADC, the State of Alaska, the U.S. Army Corps of Engineers, and MDA. As described in section 3.1.8.2, similar actions involving the developmental construction of KLC and the launch of missiles from KLC have previously undergone Coastal Consistency Determinations, resulting in decisions that activities were consistent with the state and local standards and policies. Therefore, it is anticipated that the similar construction and launch activities of the Proposed Action would be determined to be consistent with the Alaskan CZM Program and the Kodiak Island Borough Coastal Management Program.

**Operation**

*Pre-Launch Activities*

Pre-launch activity would consist of all activities required to transport missile boosters, payloads, support equipment, and essential construction materials to KLC and to assemble the major components before flight. All necessary equipment and missile components would be
transported to KLC from U.S. Government storage depots or contractor facilities by air and or barge using the Kodiak Airport and Port Facilities as the prime delivery points.

The Alternate Strategic Target System Booster Off-loading Point or the original Booster Off-loading Point would be used as a parking area utilized by military transport aircraft transporting missile payloads and/or boosters (figure 4.1.7-1). The original booster off-loading point would require the establishment and enforcement of ESQDs from the plane 434 meters (1,425 feet) to any inhabited buildings, and 260 meters (855 feet) to public traffic routes. Impacts to recreational land use would be significantly reduced by coordination with the Alaska State Parks, Kodiak Division at least 30 days before the arrival of the missile payloads and/or missile boosters to ensure the campsites within the ESQD at Buskin River State Recreation Site would be vacated. Once the boosters and payloads are removed from the immediate vicinity, ESQDs would no longer be in effect and campsites would again be accessible.

The Primary Booster Off-loading Point would be considered the preferred parking area utilized by military transport aircraft transporting missile payloads and/or boosters (figure 4.1.7-1). Although this activity would also require the establishment and enforcement of ESQDs as mentioned above, land use conflicts involving evacuation would be minimal, given that no inhabited buildings exist within the ESQD and public traffic routes would only be subject to an infrequent traffic delay of short duration. In addition, prior planning of such activity for off-peak travel hours would further serve to minimize any traffic delays.

In an effort to transport large, extremely heavy, or over dimensional items and reduce any safety and security concerns involving the use of roads from the town of Kodiak, a beach landing could be performed as a secondary delivery point for barge traffic. All three barge landing sites (shown in figure 2.3.1-1) have ample water depth to allow near shore operation and direct access to roadways that would yield immediate access to KLC. Transportation across the beach would occur over temporary 1-inch thick steel plates placed on the beach. This would help preserve the existing condition of the land and prevent erosion. Changes in land use would be due to restricting access to beach landing areas and road closures during unloading and along roadway transportation routes. Such temporary closures would not significantly affect land use. Furthermore, barge beach landings would comply completely with the standards of the Alaskan Coastal Management Program.

Storage of missiles could occur in the Integration and Processing Facility at KLC. The storage of missile propellants would occur in storage areas designed for such use in accordance with all accepted governing standards. An ESQD area would be established and maintained around facilities where ordnance is stored or handled. These operations would be considered regular actions approved by the DoD Explosive Safety Board and consistent with KLC’s land use and adjacent land use. Only the inhabited building ESQD for the GBI silos or launch pad of 434 meters (1,425 feet) would overlap the northern portion of Fossil Beach. However, public access to the beach would not be restricted due to the ESQDs, and land use would not be impacted.

**Flight Activities**

Launch preparations scheduled at KLC would follow standard evacuation procedures of the launch vicinity. The Range Safety Officer would develop a Launch Hazard Area around the proposed launch site established by AADC in accord with the Interagency Land Management Agreement for the property. All civilian, nonessential contractor, personnel, and general public
would be cleared from the Launch Hazard Area several hours before launch. Agencies that would enforce the clearance of land areas would be notified in preparation for the procedures once a test event is officially scheduled. A notice of intent to clear hazardous areas would be published in the local newspaper and broadcast in local media approximately 1 week in advance. The boundaries of the Launch Hazard Area would also be posted with notifications. Flight safety corridors would be determined for each missile flight and would be verified clear according to range safety requirements.

The availability of recreational opportunities at Narrow Cape would not be significantly impacted by the GMD ETR activities. Only temporary closures during the transportation of missile components to the launch facilities and up to a full day closure on launch days would occur for the Pasagshak Point Road at the KLC site boundary. Public access through KLC to Fossil Beach would be limited or denied for each launch day. Although these safety closures would restrict beach combing, bird and whale watching, and fishing on these days, such temporary closures would not be considered to have an appreciable impact. Furthermore, any activities that could possibly restrict access to any recreational areas would be in the newspaper and announced on the local radio. Submission of a Coastal Project Questionnaire would be coordinated among AADC, the U.S. Army Corps of Engineers, and MDA. The Coastal Project Questionnaire would be submitted to the State of Alaska to confirm that actions would be consistent with the Alaskan CZM Program and the Kodiak Island Borough Coastal Management Program.

Post-Flight Activities
As soon as the Range Safety Officer concludes that all hazardous areas are safe, all persons would be allowed to return. Only a preflight or early flight malfunction resulting in flight termination within the ROI would have any impact on surrounding land use by prolonging closures until hazardous conditions are cleared. Security requirements could require some areas to remain closed for several days following a launch.

Post-flight activities would also include removal of blast residue from the silos and/or launch pads and minor facility maintenance. These activities would have no effect on land use.

4.1.8.2.2 Target
Construction
The construction of target missile facilities is described in section 2.1.2. The immediate vicinity of the construction zone would be temporarily affected by limiting access to only necessary personnel. Nevertheless, such activity is consistent with KLC’s general land use, and would not cause any change in any use of land within or outside of KLC. The only minor conflict to land use would be the limiting of access to small portions of grazing land where the new facilities would be constructed. Therefore, no significant impacts are expected.

Under Alternative 1, internal modification would be made to the already existing Launch Pad 1’s launch service structure. Modifications would be confined to the existing Launch Pad, minimizing any possible land use changes or conflicts to land use.

Possible construction of a new Missile Storage facility, access roads north of Launch Pad 1, a Missile Assembly Building, new target pad, and Movable Missile Building would occur in the
vicinity of the northern ridge. Both construction areas would occur upon undisturbed natural grasslands and alter the land use within the immediate vicinity during construction and operation. However, such activity would not greatly reduce grazing lands and comply with the general land use and would not produce any land use conflicts within the immediate or adjacent vicinity.

Additional general infrastructure improvements such as fencing, minor road improvements, electrical service, and telephone and data transmission line installation may also be required within the construction area. Portions of such activity could be supported by barge landings and would be considered under individual site construction or general facility maintenance activities.

**Operation**

Operation of target missiles concerning land use would be similar to the operation of GBI missiles in section 4.1.8.1.

### 4.1.8.2.3 In-Flight Interceptor Communication System Data Terminal

**Construction**

The construction of a fixed or relocatable IDT at KLC would include a total disturbed area of 5.9 hectares (14.6 acres). Within this area, approximately 3.2 hectares (8 acres) would be fenced. The proposed IDT locations (figures 2.3.1-2 to 2.3.1-4) are within areas that are compliant with KLC’s general land use, and no land use conflicts would occur. Furthermore, safety precautions would be followed during operation to prevent any unidentified land use conflicts from arising.

Construction of the COMSATCOM would require a 2.8-hectare (7-acre) site surrounded by a security fence, a concrete footprint covering 0.14 hectare (0.34 acre) to accommodate the COMSATCOM and equipment, the installation of a communications cable using new and previously installed conduit, and all weather access roads. Each of the proposed locations would be compatible and related to nearby IDT facilities. Similarly, no conflicts with land use would occur.

**Operation**

*Pre-Launch Activities*

IDT components would be transported to the operation site from U.S. Government storage depots or contractor facilities by air, sea, or over land by trucks. Delivery would be conducted under routine procedures in accordance with applicable FAA and DOT safety standards to minimize any possible impacts to land use.

*Flight Activities*

Although operation of IDT and COMSATCOM facilities would only function during times of GMD exercises, installation would immediately be established and secured after delivery, limiting the access to the surrounding area. This would result in a temporary change in land use within the immediate operation area by restricting access to unauthorized personnel. However, all impacts to land use were considered in the facilities site selection and would not represent a significant impact to land use by decreasing the utilization of land nor change the general land use within or outside the boundaries of KLC.
Post-Flight Activities
Post-flight operation would include the standard maintenance procedures to secure the IDT and COMSATCOM facilities and preparation for possible relocation of the relocatable IDT. Procedures would be confined to areas already used for the establishment of such facilities and would not change or introduce a conflicting use of land within the vicinity.

A Coastal Project Questionnaire for GMD ETR activities would be submitted to the State of Alaska to confirm that construction and operation activities would be consistent with the Alaskan CZM Program and the Kodiak Island Borough Coastal Management Program. Submission of the Coastal Project Questionnaire would be coordinated between AADC, the U.S. Army Corps of Engineers, and the MDA. The previous developmental construction of KLC and activities involving the launch of missiles have undergone Coastal Consistency Determinations resulting in decisions that current activities were consistent with the state and local standards and policies; as outlined within the KLC EA (Federal Aviation Administration, 1996) and the North Pacific Targets Program EA (U.S. Army Space and Missile Defense Command, 2001b). Therefore, it is anticipated that the similar activities identified in the Proposed Action would be determined consistent with the Alaskan CZM Program and the Kodiak Island Borough Coastal Management Program.

4.1.8.2.4 Sensors

Construction
No construction would be required.

Operation

Pre-Launch Activities
Pre-launch activities would include the transportation and arrangement of four Mobile Telemetry Systems, two inside the boundaries of KLC and two others in appropriate locations on Kodiak Island. Positioning and operation would occur on a preexisting 61-meter (200-foot) by 61-meter (200-foot) level gravel area. Although an exact location of the Mobile Telemetry Systems has yet to be determined, the positioning would occur in a compatible land use area within and outside the boundaries of KLC.

Flight Activities
Operation of Telemetry Systems would be contained within the operational trailers and only occur during times of GMD exercises. Change in land use would be confined to the gravel area necessary for telemetry operations. Access to the telemetry would be limited to authorized telemetry personnel. Adjacent lands would not experience any changes or decrease in land utilization.

Post-Flight Activities
Post-flight activities would involve routine maintenance procedures in preparation for transport and possible relocation. Telemetry System components would be contained within trailers and shipped to suitable U.S. Government storage depots or contractor facilities.
4.1.8.2.5 TPS-X Radar

Construction

Alternative 1 construction would involve minor site preparations to position and create a concrete support pad for the transportable TPS-X radar and its operational components. The potential TPS-X location would be the same as described for the potential IDT and COMSATCOM site south of the Loran-C Station. Necessary EMR hazard exclusion areas would be observed in accordance with DoD and U.S. Air Force standards, and the proposed location would not produce a land use conflict.

Operation

Pre-Launch Activities
TPS-X components would be transported to the operation site from U.S. Government storage depots or contractor facilities by air, sea, or over land by trucks. Delivery would be conducted under routine procedures in accordance with applicable FAA, and DOT safety standards minimizing any possible impacts to land use.

Flight Activities
The operation of the each sensor during flight activities would only occur during times of GMD exercises. Access to the radar equipment and facilities would be limited to authorized personnel. Under the authority of the Range Safety Officer, each EMR hazard exclusion area would be cleared before operation.

Although operation of the TPS-X radar would temporarily alter land utilization by preventing encroachment into the hazard exclusion area, changes or possible conflicts to land use would be confined to the immediate operational area and the EMR hazard exclusion area. Adjacent lands would not experience any changes or decrease in land utilization.

Post-Flight Activities
Post-flight activities would involve routine maintenance procedures to secure the TPS-X radar equipment. The TPS-X components would be contained within its operational self contained trailers and shipped to suitable U.S. Government storage depots or contractor facilities. Such activity would be confined to and not affect the previously disturbed location.

4.1.8.3 Alternative 2

Alternative 2 would be similar to Alternative 1 without GBI, IDT, and TPS-X facilities.

4.1.8.3.1 Targets

Under Alternative 2, GMD activities and potential impacts involved in the construction and operation of target missile facilities would be the same as described under Alternative 1 in section 4.1.8.2.2.
4.1.8.3.2 Sensors

Under the Proposed Action of Alternative 2, GMD activities and possible impacts involved in the operation of sensory equipment within and outside the boundaries of KLC would be the same as described under Alternative 1 in section 4.1.8.2.4.

4.1.8.4 Alternative 3

Land use impacts due to construction and operation of GBI, target, IDT, and sensors, and their accompanying facilities for Alternative 3 would be as described for Alternative 1.

4.1.8.5 Cumulative Impacts

The KLC EA indicated no significant impact to land use from nine annual launches (Federal Aviation Administration, 1996). It is not likely that the Proposed Action of up to five launches (GBI and/or target), in conjunction with other currently planned or anticipated launches at KLC, would exceed nine launches per year, the level of activity analyzed in the KLC EA. The total existing ground disturbances associated with current facilities and activities is approximately 1 percent of the 1,504 hectares (3,717 acres) leased by the AADC for KLC. Site preparation and new construction activities associated with the Proposed Action would disturb less than 2 percent of the total or 26 hectares (64.2 acres). The total cumulative impact of such actions would be less than 3% of the KLC’s total land or approximately 43 hectares (106 acres).

4.1.8.6 Mitigation Measures

No land use mitigation measures are proposed for the GMD ETR activities at KLC.

4.1.9 NOISE—KODIAK LAUNCH COMPLEX

This section addresses the potential impacts to the noise environment due to the construction and operation of the GBI, target, IDT, and sensor elements of the ETR at KLC, as well as the identification of potential cumulative impacts and mitigation measures.

The analysis in this section is concerned with human receptors; noise effects on wildlife are discussed in section 4.1.3, Biological Resources.

4.1.9.1 No Action Alternative

Missile Defense Agency

Under the MDA’s No Action Alternative, launches would continue to occur at KLC, although the GMD ETR would not be established, and there would be no change to noise at KLC. The GMD ETR would not be established and GBI and target launch scenarios would not be tested under more operationally realistic conditions. Current activities of single target and commercial launches would continue.

Under the KLC site license, an Environmental Monitoring Plan was required as part of the KLC launch site operator license and called for the monitoring of at least the first five launches from KLC. Results from noise monitoring are shown in table 4.1.9-1 for the ait-1, ait-2, QRLV, and
Athena-2 (data were not gathered for the fifth launch, Strategic Target System, due to adverse weather conditions). These levels were recorded at Ugak Island, approximately 5.6 kilometers (3.5 miles) from the launch pad.

These levels would be audible for only short periods of time and would not be expected to interfere with the area’s fishing, camping, or other recreational uses. (U.S. Department of the Air Force, 2001)

**Federal Aviation Administration**

Under the FAA’s No Action Alternative, the launch site operator license for KLC would not be renewed and no launches would be allowed to occur from KLC after September 2003. Therefore, no impacts from noise from launches would occur at KLC.

**4.1.9.2 Alternative 1**

Alternative 1 includes the construction of numerous facilities as described in section 2.3.1.1. Construction at KLC would be temporary in nature and similar to any commercial construction site. Noise generated during construction should have minimal impact to offsite areas.

**4.1.9.2.1 Ground-Based Interceptors**

**Construction**

Construction would result in intermittent, short-term noise effects that would be temporary, lasting for the duration of the noise generating construction activities. Noise-generating construction activities would include excavation and grading, utility construction and paving, and frame building.

The specific types of equipment that would be used during these construction phases are not known at this time. Excavation and grading would normally involve the use of bulldozers, scrapers, backhoes, and trucks. The construction of buildings would likely involve the use of pile drivers, concrete mixers, pumps, saws, hammers, cranes, and forklifts. Typical sound levels from construction equipment are listed in table 4.1.9-2.

It is assumed that construction would take place 24 hours per day during the summer due to the shortened construction season in Alaska. Therefore, due to the 10 dBA penalty added to nighttime noise, the 65 dBA and 75 dBA contours are estimated to occur within approximately 152 meters (500 feet) and 122 meters (400 feet) from the construction site, respectively. Therefore, no impacts to the noise environment would be expected from construction equipment noise.

Source: Federal Aviation Administration, 1996

Due to the exclusion of the public from the immediate vicinity of the construction site, the public would not be exposed to hazardous noise levels. However, the public within a few kilometers (miles) of KLC would be subject to noise that could decrease the existing aesthetic quality. The nearest residence is approximately 3 kilometers (2 miles) from KLC. Individuals living near the Pasagshak Point Road would experience a slight increase in traffic noise.

Operation

Pre-Launch Activities

Noises produced during pre-launch activities include noise from mechanical equipment such as worker vehicles, trucks, and by the use of the public address systems. Transportation noise would increase, as up to 235 launch support personnel drive to the site and additional trucks bring material to the site. However, this increase is expected to be reduced as some personnel are expected to be housed onsite at the proposed mancamp and at the existing mancamp at Kodiak Ranch. The remainder would commute from accommodations elsewhere on Kodiak. The increase in traffic noise levels due to launch support personnel would be considered temporary and would not permanently impact the aesthetic quality of the surrounding area.

Launch Activities

Noise during launch activities includes the GBI launch itself, which is a result of the interaction of the exhaust jet with the atmosphere and the combustion of the fuel. The sound pressure from a missile is related to the engine’s thrust level and other design features.

Personnel would normally be at the Launch Control Center during launches. At approximately 3 kilometers (2 miles) from the launch pad, they would be exposed to approximately 118 dBA.
during a single launch. This value is within the OSHA standard of 118 dBA over 9.6 minutes (U.S. Department of Labor, 2002). In the event of a dual GBI launch, personnel located at the Launch Control Center are anticipated to be exposed to approximately 121 dBA. This level is within the OSHA standard of 121 dBA over 6.6 minutes. Although no standards exist for single-event noise exposure, a time-weighted average of 90 dBA is established as a limit for an 8-hour exposure. However, workers exposed to excessive launch noise would be required to wear hearing protection.

In addition to the noise of the rocket engine, sonic booms are possible. A sonic boom is a sound that resembles rolling thunder, and is produced by a shock wave that forms at the nose of a vehicle that is traveling faster than the speed of sound. However, GBI launches would be in a southerly direction, and a sonic boom would not occur over land. Sonic booms are not expected to impact Kodiak Island or Ugak Island. Vessels impacted by sonic booms would be expected to experience sound resembling mild thunder.

All public, civilian, and nonessential personnel would be required to be outside of the Ground Hazard Area where the expected noise levels would be below the 115 dBA limit for short-term exposure. Given the infrequency of the launches, the short duration of the launch, and the similarity to previous launches, adverse noise impacts from launch activities are not anticipated.

**Post-Launch Activities**
Noise generated during the removal of all mobile equipment and assets during post-launch activities should have minimal impact to the noise environment on or off of KLC.

**4.1.9.2.2 Targets**

**Construction**
Noise caused by construction of target facilities would be similar to that described in section 4.1.9.2.1 for GBI facility construction.

**Operation**

**Pre-Launch Activities**
Pre-launch activities would include noise from mechanical equipment and the increase in vehicles for transportation of personnel to KLC. Personnel transportation noise is expected to be moderate due to some personnel being located onsite at the proposed mancamp and the existing mancamp at Kodiak Ranch. The increase in traffic noise levels due to target launch support personnel would be considered temporary and would not permanently impact the aesthetic quality of the surrounding area.

**Launch Activities**
The launch vehicle boosters are the major source of target operational noises. Based on the duration of a launch, an A-weighted scale is used and dBA measurements are used to adequately characterize the operational noise. $L_{\text{max}}$ is used to compare noise levels due to its ability to cover the entire sound spectrum, especially sounds audible to humans. Table 4.1.9-3 lists previous launch $L_{\text{max}}$ levels as well as predicted levels for proposed targets. Also listed in
the table 4.1.9-3 are $L_{\text{max}}$ levels for the Castor 120™ motor. The Castor 120™ motor was analyzed in the KLC EA and found not to produce adverse noise levels.

Figure 4.1.9-1 shows predicted launch noise levels, including Strategic Target Systems, Peacekeeper Targets, and measured noise levels of a previous Athena-2 launch.

It is expected that these noise levels for single target launches would be audible for only short periods of time and would not be expected to interfere with the area’s fishing, camping, or other recreational uses. Figure 4.1.9-2 depicts calculated noise levels of a simultaneous dual Strategic Target System, Peacekeeper Target, and Athena-2 launches. Dual target launches are expected to occur virtually simultaneously. It is anticipated that noise impacts for dual launches would also fall within OSHA limits.

Figure 4.1.9-2

Noise Levels
Calculated for Dual Launches
4.1.9.2.3  In-Flight Interceptor Communication System Data Terminal

Construction and operation of an IDT at KLC would have minimal impact to the surrounding environment’s noise levels. Construction noises would include noise from mechanical equipment. Noises involving traffic increases are included in analysis for GBI construction. Operational noise levels of an IDT are anticipated to be from the use of a 275-kW generator in the event of a loss of power. The IDT itself would produce minimal noise levels. Therefore, noise levels from the operation of an IDT would not increase the noise levels of the regional environment.

4.1.9.2.4  Sensors

Noise from the preparation of two gravel pads for mobile telemetry would be from the use of mechanical equipment. Exact types of equipment to be utilized are not known at this time. Typical sound levels from possible construction equipment are listed in table 4.1.9-2. It is expected that the two 10-kW generators to be used for mobile telemetry would produce noise levels less than that of normal speech. Noise levels from the operation of these systems would not increase the noise levels of the regional environment.

4.1.9.2.5  TPS-X

The TPS-X construction and operation requirements and potential impacts to noise levels would be similar to that described previously for sensors. Exact types of equipment to be used for construction are not known at this time; however, typical sound levels from possible construction equipment are listed in table 4.1.9-2. Operational noise levels of an IDT are expected to stem from the use of a 1.5-MW generator. Most 1.5-MW generators are equipped with attenuations equipment to reduce noise levels. Therefore, noise levels from the operation of the TPS-X would not increase the noise levels of the regional environment.

4.1.9.3  Alternative 2

4.1.9.3.1  Targets

Noise impacts due to construction and operation activities for target launches from KLC would be similar to those described in section 4.1.9.2.2 for Alternative 1.

4.1.9.3.2  Sensors

Sensor setup and operation activities would impact the surrounding noise environment as described in section 4.1.9.2.4 for Alternative 1.

4.1.9.4  Alternative 3

Noise impacts due to construction and operation of GBI, target, IDT, and sensors and their accompanying facilities for Alternative 3 would be similar to those described in section 4.1.9.2 for Alternative 1.
4.1.9.5 Cumulative Impacts

Construction at KLC for GMD ETR activities would cause a short-term temporary increase in the noise levels in the immediate vicinity of the construction work. This effect would be localized, and is not anticipated to cause permanent noise level impacts.

Since the sound level generated by each launch is a short, discrete event, the potential cumulative impacts to noise from GMD ETR launches would not be substantial. The KLC EA indicated no significant noise impacts to sensitive receptors for nine annual launches (Federal Aviation Administration, 1996). It is not likely that the Proposed Action of up to five launches (GBI and/or target) in conjunction with other currently planned or anticipated launches at KLC would exceed nine launches per year, the level of activity analyzed in the KLC EA. Therefore, no cumulative noise impact is anticipated at KLC.

4.1.9.6 Mitigation Measures

No noise mitigation measures are proposed for the GMD ETR activities at KLC.

4.1.10 SOCIOECONOMICS—KODIAK LAUNCH COMPLEX

General socioeconomic impacts resulting from the Proposed Action can lead to an economic gain or loss for the community or area. Potential socioeconomic impacts of the project stem from construction or operational activities, the duration and extent of displacement or modification of existing activities, and diversion or temporary suspension of access associated with the Proposed Action. Impact analysis is focused on the following broad areas of economic or social impacts: displacement of populations, residences or businesses; housing/accommodation availability; employment and income; growth inducement; and potential impacts to locally significant industries such as tourism, commercial fishing, or agriculture.

4.1.10.1 No Action Alternative

Missile Defense Agency

Under the MDA’s No Action Alternative, launches would continue to occur from KLC, but the GMD ETR would not be established and interceptor and target launch scenarios would not be tested under more operationally realistic conditions. No displacement of populations, residences, or businesses would occur within the Kodiak Island Borough as a result of the MDA’s No Action Alternative. Under the MDA’s No Action Alternative there would continue to be a need for local temporary accommodation of personnel associated with launches. Under the current FAA launch site operator license there could be up to nine launches per year from KLC. Given the extent of local facilities, this is not anticipated to be a significant impact.

Though limited in scope, this alternative would nonetheless have a continued limited positive effect on the local economy of the Borough by the ongoing local service-based employment opportunities and through launch personnel spending money in the local economy. The overall impact would be slight and would not be expected to cause any population growth. No significant impacts to the commercial fishing or fish processing industries, tourism, or logging industries are anticipated. No significant socioeconomic impacts would occur, and no mitigation measures are proposed.
Federal Aviation Administration

Under the FAA’s No Action Alternative, the launch site operator license for KLC would not be renewed and no launches would be allowed to occur from KLC after September 2003. Any economic benefits to the Kodiak Island Borough from the periodic presence of launch-related personnel would not occur.

4.1.10.2 Alternative 1

4.1.10.2.1 Ground Based Interceptor

Construction

Implementation of Alternative 1 would result in construction of two GBI silos or one launch pad and associated support facilities and ancillary equipment and modifications to some existing facilities. Approximately 100 construction personnel would be required on Kodiak Island during the course of construction of new facilities and modification of existing facilities. Construction equipment and materials would be shipped via sea or air to Kodiak Island. Local procurement of materials and workers is expected to remain very limited, and while positive, would not represent a significant economic impact to the borough.

Construction activities related to the implementation of Alternative 1 would not cause any displacement of populations, residences, or businesses within Kodiak Island Borough. The duration of construction activities is expected to last 15 months. The accommodation needs of the additional personnel during this period would be met via local hotels and guesthouses. Given the extent of available facilities in Kodiak, this is not considered a potentially significant economic impact. Coordination with existing accommodations would be carried out to maximize their use while minimizing any potential long-term impacts.

The additional construction personnel, by spending money in the local economy, mainly via accommodation and procurement of goods and services, would represent both a potential increase in local service-based employment opportunities and a small but positive temporary economic impact to the local community. The overall impact would, however, be slight and would not cause any population growth. No significant impacts to locally significant businesses or industries such as commercial fishing, fish processing, tourism, or logging are anticipated during construction activities. Also, personnel would be restricted to KLC during working hours and significant impacts to subsistence hunting, recreational hunting, hiking, or other recreational activities or areas are not anticipated. No significant socioeconomic impacts would occur through the construction activities associated with Alternative 1.

Operation

Pre-Launch, Flight, and Post-Flight Activities

Implementation of Alternative 1 would result in single and dual GBI launches from KLC. Interceptor missile boosters, payloads, and support equipment would be transported by air or ship from Government storage depots or contractor facilities to KLC. There would be a total of five GMD missile launches per year from interceptor and/or target missiles. A typical ramp up over a 3-month period would be 55, 120, and 235 personnel who would be required at KLC to support a dual interceptor launch. After an interceptor launch, the majority of these personnel would immediately depart KLC and Kodiak Island.
As part of pre-launch and flight activities, a Launch Hazard Area and flight safety zone would be established in accord with AADC’s Interagency Land Management Agreement for Narrow Cape, which provides for public access except in cases of danger and for protection of structures. These areas would be cleared approximately 1 to 4 hours before a launch. The actual launch is expected to last approximately 30 minutes. Upon the Range Safety Officer declaring the area safe after a launch, expected to be within hours, the areas can then be reoccupied. The notice given to the local communities via local newspapers, broadcast media, and commercial fishing and tourist boat trade associations would be extensive. As such, entities with an economic interest in the use of these areas such as the commercial fishing, aviation, and tourist industries of Kodiak would not be significantly impacted by the proposed clearance areas.

Personnel would reside offsite at local hotels and guesthouses to support a GBI launch. As outlined in section 3.1.10, Kodiak has approximately 250 hotel, motel, and guesthouse rooms. There are approximately 100 additional rooms within the Narrow Cape Lodge (56) and U.S. Coast Guard accommodation facilities (44). Additional rooms could be obtained through an addition to the Narrow Cape Lodge (approximately 60 rooms) and/or constructing a mancamp on KLC (approximately 60 rooms). Without the construction of additional facilities, the accommodation needs of as many as 235 additional personnel necessary to support a dual interceptor launch would represent a positive economic impact to the local economy during the tourist “off-season” period (from September to March), given both the current supply of rooms in Kodiak and the historically low vacancy rates during this time. With regard to pre-launch periods occurring during tourist “high-season” (from May to September), the accommodation needs of up to 235 personnel, without the construction of additional facilities, would represent a positive economic impact to the community; however, there could be a potential impact to the repeat/returning tourist clientele. In order to minimize any potential negative impacts during these months, every effort would be made to secure as many rooms as possible at alternate facilities to those used by visiting tourists. Coordination with existing accommodations would be carried out to maximize their use while minimizing any potential long-term impacts.

Generally, by spending money in the local economy, mainly via accommodations and the normal procurement of goods and services, the additional personnel would represent both a potential increase in local service-based employment opportunities and a positive economic impact to the local community for the duration of their stay. The overall impact would be moderate, and although each launch would represent a positive impact of several million dollars on the Kodiak economy, it would not cause any population growth. No population, housing or businesses would be displaced during operational activities. No significant impacts to locally significant businesses or industries such as commercial fishing, fish processing, tourism, or logging are anticipated during operational activities. Also, personnel would be restricted to KLC during working hours and significant impacts to subsistence hunting, recreational hunting, hiking, or other recreational activities or areas are not anticipated. Other than potential shortage of accommodations, no negative socioeconomic impacts would occur through the operational activities associated with Alternative 1.

4.1.10.2.2 Target Construction

Implementation of Alternative 1 would result in construction of a target launch pad and associated support facilities and ancillary equipment and modifications to some existing facilities. Approximately 100 construction personnel would be required on Kodiak Island during
the course of construction of new facilities and modification of existing facilities. Construction equipment and materials would be shipped via sea or air to Kodiak Island. Local procurement of materials and workers is expected to remain limited and while positive would not represent a significant economic impact to the borough.

Construction activities related to the implementation of Alternative 1 would not cause any displacement of populations, residences, or businesses within Kodiak Island Borough. The duration of construction activities is expected to last 12 to 15 months. The accommodation needs of the additional personnel during this period would be met via local hotels and guesthouses. Given the extent of available facilities in Kodiak, this is not considered a potentially significant economic impact.

No population, housing or businesses would be displaced. An adequate supply of accommodation for construction personnel would be available and would consequentially represent a positive temporary economic impact to the local community. The overall impact would, however, be slight and would not cause any population growth. No significant impacts to locally significant businesses or industries are anticipated during construction activities. No significant socioeconomic impacts would occur through the construction activities associated with Alternative 1.

Operation

**Pre-Launch, Flight, and Post-Flight Activities**

Implementation of Alternative 1 would result in single and dual target launches from KLC. Target missile components would be built in contractor facilities and delivered to KLC via air or boat for system assembly and checkout. When a target missile test flight is planned, the same type of land and water clearance areas that were defined for the GBI would be established and cleared for the target missile. Again, entities with an economic interest in the use of these areas such as the commercial fishing and tourist industries of Kodiak would not be significantly impacted by the proposed clearance areas.

There would be a total of five GMD missile launches per year from interceptor and/or target missiles. A typical ramp-up over a 3-month period for a single target missile launch would be 25, 55, and 110 personnel who would be required at KLC to support a target launch. After a target launch, the majority of these personnel would immediately depart KLC and Kodiak. Requirements for a dual target launch would be 25, 75, and 150 personnel.

Personnel would reside offsite at local hotels and guesthouses to support a target launch. Approximately 250 hotel, motel, or guesthouse rooms are in Kodiak. There are approximately 100 additional rooms within the Narrow Cape Lodge (56) and U.S. Coast Guard accommodation facilities (44). Additional rooms would be obtained through an addition to the Narrow Cape Lodge (approximately 60 rooms) and/or constructing a mancamp on KLC (approximately 60 rooms). Without the construction of additional facilities, the accommodation needs of up to 150 additional personnel during the tourist “off-season” (from September to March) would represent a positive economic impact to the local economy given both the current supply of rooms in Kodiak and the historically low vacancy rates during this time. With regard to pre-launch periods occurring during tourist “high-season” (from May to September), the accommodation needs of up to 150 personnel, without the construction of additional facilities, would represent a positive economic impact to the community; however, there could be a potential impact to the
repeat/returning tourist clientele. In order to minimize any potential negative impacts during these months, every effort would be made to secure as many rooms as possible at alternate facilities to those used by visiting tourists.

Generally, by spending money in the local economy, mainly via accommodations and the normal procurement of goods and services, the additional launch-related personnel would represent both a potential increase in local service-based employment opportunities and a positive economic impact to the local community for the duration of their stay. The overall impact would be moderate, and although each launch would represent a positive impact of several million dollars on the Kodiak economy, it would not cause any population growth. No population, housing, or businesses would be displaced during operational activities. No significant impacts to locally significant businesses or industries such as commercial fishing, fish processing, tourism, or logging are anticipated during operational activities. Also, personnel would be restricted to KLC during working hours and significant impacts to subsistence hunting, recreational hunting, hiking, or other recreational activities or areas are not anticipated. Other than the potential shortage of accommodations, no significant socioeconomic impacts would occur through the operational activities associated with Alternative 1.

4.1.10.2.3 In-Flight Interceptor Communication System Data Terminal

Construction

Implementation of Alternative 1 would result in the construction of an IDT on KLC. The IDT would be located near the Loran Station, the Oxidizer Storage Facility, or near the entry road. Construction equipment, materials, and personnel would arrive at KLC as part of the construction of the GBI silos and associated support equipment. The construction personnel and related construction equipment identified for GBI would be involved in the construction of the IDT.

Construction activities related to the implementation of Alternative 1 would not cause any displacement of populations, residences, or businesses within Kodiak Island Borough. The presence of the construction personnel represents both a potential increase in local service based employment opportunities and a small but positive temporary economic impact to the local community. The overall impact would however be slight and would not cause any population growth. No significant impacts to businesses or industries such as commercial fishing, fish processing, tourism, or logging, are anticipated during construction activities. No significant socioeconomic impacts would occur due to the construction activities associated with Alternative 1.

Operation

The IDT site would require three onsite support personnel when in operation. The generator would be tested weekly during non-launch periods and during power outages, approximately 250 hours a year. The personnel associated with the permanent IDT would be part of the people required to support an interceptor launch and the extent of the related economic impacts would remain the same. The proposed activities would not cause any population growth or displacement of populations, residences, or businesses within Kodiak Island Borough. Similarly, no significant impacts to businesses or industries are anticipated. No significant socioeconomic impacts would occur thorough the IDT operational activities associated with Alternative 1.
4.1.10.2.4 Sensors

Construction

These systems are mobile and would be brought to the vicinity of the launch site approximately 2 to 6 weeks before the planned launch. No construction activities would be involved and no socioeconomic impacts would occur.

Operation

Implementation of Alternative 1 would include the operation of sensors. Instrumentation associated with the launch of a target missile would include two telemetry sites and a range control support equipment site. These systems would be transported to Kodiak and remain in position until the launch event has been complete. In most cases the equipment would be removed within days after the launch.

The personnel associated with the launch of a target missile would operate these systems; therefore, no personnel in addition to those already involved in target operations would be needed to operate the sensors, and the extent of the related economic impacts would remain the same. The proposed activities would not cause any population growth or displacement of populations, residences, or businesses within Kodiak Island Borough. Similarly, no significant impacts to businesses or industries are anticipated. Under Alternative 1, no significant socioeconomic impacts would occur through the operational activities associated with sensors.

4.1.10.2.5 TPS-X Radar

Construction

The Proposed Action would require minor site preparation to construct a single concrete support pad for the transportable TPS-X radar and its operational components. The proposed location is the potential IDT site south of the Loran-C Station. Construction equipment, materials, and personnel would arrive at KLC as part of the construction of the GBI silos, and associated support equipment. No socioeconomic impacts would occur from such minimal construction activities.

Operation

The TPS-X would be transported to KLC by air or land and then transported to the potential site by truck. The personnel associated with the launch of a GBI missile would operate these systems; therefore, no additional personnel would be needed and the extent of the related economic impacts would remain the same. The proposed activities would not cause any population growth or displacement of populations, residences, businesses, or industries are anticipated. No significant socioeconomic impacts would occur through the operational activities associated with Alternative 1.

4.1.10.3 Alternative 2

Under Alternative 2, GBIs would be launched from Vandenberg AFB instead of KLC. Thus, there would be no construction or operations related to either GBI silos and their associated support equipment or an IDT on KLC. However, the other components described in Alternative 1, and the extent of the related impacts, would remain the same.
4.1.10.3.1 Target

The socioeconomic impacts to Kodiak Island from construction of a target launch pad and associated support facilities and the launch of single and dual targets from KLC would be similar to what was discussed in section 4.1.10.2.2.

4.1.10.3.2 Sensors

The socioeconomic impacts to the Kodiak Island from construction of a target launch pad and associated support facilities and the launch of single and dual targets from KLC would be similar to what was discussed in section 4.1.10.2.4.

4.1.10.4 Alternative 3

For Alternative 3, socioeconomic impacts due to construction and operation of GBI, target, IDT, and sensors, as well as their accompanying facilities, would be the same as described in section 4.1.10.2 for Alternative 1.

4.1.10.4.1 Cumulative Impacts

It is not likely that the Proposed Action of up to five launches (GBI and/or target) in conjunction with other currently planned or anticipated launches at KLC would exceed nine launches per year, the level of activity analyzed in the KLC EA. Other than those activities already described, no other activities have been identified that would combine with the Proposed Action and result in cumulative socioeconomic impacts.

4.1.10.4.2 Mitigation Measures

No socioeconomic mitigation measures are proposed for the GMD ETR activities at KLC. Coordination with the local tourist industry is a typical practice that would be used to reduce the potential impact on tourists during the peak tourist season. The construction of an addition to the existing Narrow Cape Lodge and/or the construction of an additional mancamp at KLC are alternatives that could be implemented. If a decision is made to proceed with proposed activities at KLC, then the housing availability and requirements would be reviewed at that time, and a decision would be made regarding this construction.

4.1.11 TRANSPORTATION—KODIAK LAUNCH COMPLEX

4.1.11.1 No Action Alternative

Missile Defense Agency

Under the MDA’s No Action Alternative, launches would continue to occur from KLC, but the GMD ETR would not be established and interceptor and target launch scenarios would not be tested under more operationally realistic conditions. The AADC and the Alaska Department of Transportation and Public Facilities conducted studies of the roads, bridges, and culvert crossing conditions and determined that they are adequate for motor loads as heavy as a Castor 120™ (Alaska Aerospace Development Corporation, 2001).
Federal Aviation Administration

Under the FAA’s No Action Alternative, the launch site operator license for KLC would not be renewed and no launches would be allowed to occur from KLC after September 2003. Therefore, there would be no impacts to transportation from launches at KLC.

4.1.11.2 Alternative 1

4.1.11.2.1 Ground-Based Interceptors

Construction

Implementation of Alternative 1 would result in the construction of facilities as described in section 2.3.1.1. Kodiak Island and KLC have established air, ocean, and ground transportation systems. The construction equipment and materials would be brought to Kodiak Island by ocean carrier or by plane and transported over land or via barge/beach landing to KLC. Kodiak Island is already one of the leading shipping ports in southwest Alaska and as a commercial service facility is equipped to accommodate international cargo receipt and shipment. Scheduled service is in place to support the normal level of traffic; however, peak demands are anticipated and scheduled in advance. In addition, vessels serving the AMHS are rarely booked full to capacity with container vans (Alaska Department of Transportation and Public Facilities, 1998). These activities would be considered normal usage and would not result in an impact to the ocean transportation systems. Approximately 100 construction personnel would be brought to Kodiak Island via the AMHS and/or commercial airliner. Year-round service to Kodiak Island by sea and air currently exists, and movement of project-related people would not impact either of these transportation systems.

Once unloaded at Kodiak Island, construction equipment and material could be shipped by tractor-trailer transport to KLC with beach landings as a possible option. Roadway access to KLC is via Rezanof Drive West. This road is narrow and, in some cases, steep. There are switchbacks and 11 bridge crossings before reaching KLC. Due to the nature of these road conditions, movement of construction equipment and material would cause temporary traffic delays; however, these delays would be minimal and infrequent. Public announcements regarding potential delays would be made, and movements during off-peak travel hours would be scheduled to the greatest extent possible.

The roadways supporting the individual facilities within KLC are designed to accommodate tractor-trailer transport vehicles as well as passenger vehicles and light trucks. Road grades range from 1 percent to over 15 percent. Due to the nature of these road conditions, project-related movements would also cause temporary traffic delays within KLC; however, they would not extend to local roads. Development of these new facilities would result in the construction of new roads, parking for staff vehicles and tractor trailers, and upgrades to existing roads. The approximately 100 construction personnel would be housed in Narrow Cape Lodge and accommodations in the Kodiak area. The proposed Narrow Cape Lodge expansion, and/or the proposed mancamp would further decrease the transportation to and from Kodiak proper; thus the increase in personnel would only minimally change the ADT on key local roads, if at all, and the impact on Level of Service would be negligible.

Potential beach landing areas, for optional barge delivery, include Burton Ranch Beach (mancamp location), Boulder Beach (near Bear Paw Ranch), and Pasagshak Beach (near the
Pasagshak Recreation Area). The Narrow Cape Lodge is an example of direct barge delivery to KLC. For the latter two locations, some modification would be necessary: Boulder Beach would require a temporary ramp; Pasagshak Beach would require widening of a turn to allow access to the main road nearby. Temporary beach closure would be necessary, but would be considered routine and of short duration.

**Operation**

*Pre-Launch Activities*

Implementation of Alternative 1 would result in single and dual GBI launches from KLC. Interceptor missile boosters, payloads, and support equipment would be transported by air or ship/barge from Government storage depots or contractor facilities to KLC. All shipping would be conducted in accordance with DOT regulations. Applicable safety regulations would be followed in the transport and handling of hazardous materials. The interceptor may arrive at Kodiak with the EKV attached, or the booster may be shipped separately from the EKV. In either case, integration and assembly operations would be performed onsite. There would be up to five interceptor launches per year; however, as previously stated, Kodiak Island is one of the leading shipping ports in southwest Alaska and as a commercial service facility is equipped to accommodate this type of cargo and frequency of shipping.

As mentioned in section 4.1.7.2.1, use of the Kodiak State airport could be required to support receipt and transportation of missile components and mission personnel. This is typical procedure for rocket motor shipments to KLC, and, if chosen, appropriate safety measures (as established by AADC) would be instituted at the receiving terminals or airport, including specified receiving and parking areas (for transport vehicles), establishment and enforcement of applicable ESQDs around receiving areas, restricting handling and transportation of missile components to specific and properly trained personnel, and using established and permitted transportation routes from the receiving terminal or airport to KLC.

A Primary or Alternate Booster Off-loading Point (figure 4.1.7-1) could be utilized by military aircraft transporting missile payloads and/or boosters. An ESQD would be established around such aircraft to a distance of 434 meters (1,425 feet) to any inhabited buildings and 260 meters (855 feet) to any public traffic routes. Selection of the Primary Booster Off-loading Point would result in the temporary closure of portions of Airport Terminal Road and possibly a small portion of Buskin River Road. Selection of the alternate scenario would result in the temporary closure of the areas surrounding the junction of Buskin River Road and Buskin Beach Road, as well as the area just southwest of this junction, which includes the eastern portion of Airport Terminal Road.

With either scenario, traffic delays would be discrete and infrequent, and impacts to transportation on these non-primary roads would be significantly reduced by coordination with the Alaska State Parks, Kodiak Division. In keeping with this, AADC would provide a 30-day advance notice regarding any closure prior to the arrival of missile payloads and/or boosters in order to ensure that roadways at or near the recreation site that fall within the ESQD would be vacated. Once the boosters and payloads are removed from the immediate vicinity, ESQDs would no longer be in effect and roadways would again be accessible. Effects on Buskin River Road, Buskin Beach Road, and Airport Terminal Road would be minimal. In addition, prior planning of such activity for off-peak travel hours would further serve to minimize any traffic delays.
Once unloaded at Kodiak Island, the interceptor missile boosters, payloads, and support equipment would be shipped by tractor-trailer transport to KLC in a manner similar to that of the construction equipment and materials; as an option, they could be barged via one of the aforementioned potential beach landing areas. The Alaska Department of Transportation and Public Facilities has evaluated all of the bridges on this road and made improvements to them to support rocket motors in transport to KLC (Alaska Aerospace Development Corporation, 2001). Due to the nature of these road conditions, movement of interceptor missile boosters, payloads, and support equipment would cause temporary traffic delays; however, these delays would be minimal and infrequent. Prior planning of these movements for off-peak travel hours would further serve to minimize these delays. Once at KLC, the interceptor would be placed in secure storage until assembly and launch preparation. Due to the nature of the road conditions within KLC, movement of these vehicles would also cause temporary traffic delays, but they would not extend to local roads. As mentioned, utilizing the beach landing/barging options would require modifications. Temporary beach closure would be necessary, but would be considered routine and of short duration.

A typical manpower build-up over a 3-month period would be 55, 120, and 235 personnel who would be required at KLC to support a dual interceptor launch. They would come to Kodiak via commercial airliner or the AMHS. It is assumed that approximately 50 personnel would be housed at the existing mancamp on Kodi Ranch. If the additional mancamp is not constructed on KLC or the existing mancamp is not added on to, then it is conservatively estimated that the remaining 185 personnel would commute daily to KLC from accommodations in the surrounding areas and within the City of Kodiak during a peak month. This would add approximately 93 vehicles (assuming 2 persons per vehicle) to Rezanof Drive West each day during peak hours. Although the local road system would experience an increase in traffic, the increase would only minimally change the ADT on key local roads, and the impact on Level of Service would be negligible. The use of an onsite mancamp and/or expansion of the Narrow Cape Lodge to house personnel would also help to reduce automobile traffic between the worksite and the city of Kodiak, lowering the potential impacts even further.

**Flight Activities**

When a missile test flight is planned, there are certain areas where missile components and debris are expected to impact: the booster drop zone and the debris impact area. These areas are cleared of personnel as part of the test plan. There are other areas where debris may land if the test does not proceed as planned. These areas of the test event may be subject to the risk of mishap from a flight termination. Each missile flight test event would be modeled using computer predictions of the behavior of the missiles. Specific clearance areas would be defined for each flight test depending upon the profile of that test.

Once a test event is scheduled, there would be a standard sequence of notification and coordination procedures between the Range Safety Office and the agencies (FAA, Coast Guard, AMHS) that would enforce the clearance of land, air, and sea areas. The date and location of scheduled flight tests or training events would be published approximately one week in advance as described below for land, air, and sea areas. Clearances are of a short duration, and effects are anticipated to be negligible.

Land areas would be cleared by KLC Security personnel approximately 4 hours before launch. A Launch Hazard Area would be established around the launch site; however, since the launch
Azimuth for KLC is southwest and southeast over the Pacific Ocean and would not be over any public roads, there would be no impact to road transportation.

Impacts to commercial aviation and airspace from missile launches are evaluated in section 4.1.2.

Sea-surface areas that would have to be cleared include the Launch Hazard Area that extends overwater, the predicted booster drop zones, the predicted debris impact area, and the predicted whole body miss impact point for each missile. Sea-surface areas would be cleared with the cooperation of the U.S. Coast Guard. Sea-surface areas would need to be cleared in advance of a planned test event to allow sufficient time to ensure that it is indeed clear; this would be approximately 4 hours before test launch. The U.S. Coast Guard would publish a NOTMAR to clear certain sea-surface areas for safety reasons. Notice of intent to clear certain sea-surface areas for safety reasons would be published in local newspapers, broadcast in local news media, and distributed to commercial fishing and tourist boating trade associations. Subject to the conditions of appropriate Memoranda of Agreement, Coast Guard officials would close the sea-surface area(s) up to 4 hours before the planned launch and then survey them to ensure that they are clear of ships or watercraft. Coast Guard boats and range safety aircraft would patrol the area to ensure that it is clear of ships or watercraft. The AMHS ferry route is north of Kodiak and away from the KLC launch azimuth; therefore, no impacts to vessels traveling these routes would occur. The Pacific Ocean south of Kodiak does contain commercial shipping lanes for vessels traveling from Seattle to and from Nome and Yokohama. These vessels would be required to stay clear of these areas during a launch, which could cause them to be slightly delayed. These delays would be short-term and infrequent (up to five times per year), however, and the advanced notification would serve to further minimize any impact. Commercial and recreational fishing vessels would also be required to relocate their activities during a launch event; however, they would only be required to move for a short period of time and this would only occur infrequently (up to five times per year). Section 4.1.10 includes a more detailed analysis of the impacts to commercial and recreational fishing from the implementation of this alternative.

**Post-Flight Activities**

After completion of a missile flight test, the clearance areas would be released, or allowed to be re-occupied. The Range Safety Officer would do this as soon as he or she was assured that any hazardous aspect of the test was completed. Such residual hazardous concerns may include the presence of hazardous debris, debris still falling after an intercept, or other potentially dangerous consequences. Notification would be by radio, telephone, or computer to aviation and maritime authorities. If required, debris recovery on land may involve the use of helicopters and off-road vehicles, and the two main parachutes, if used to air-launch targets for interceptor tests, would be recovered from ocean drops. This debris cleanup would not have any impact on land-, air-, or sea-based transportation systems. After an interceptor launch, personnel would depart KLC and Kodiak by commercial air or sea (via the AMHS).

**4.1.11.2 Target Construction**

Implementation of Alternative 1 would result in the construction of facilities as described in section 2.3.1.1. The construction equipment and personnel associated with the construction of
the target pads and associated support facilities would be similar to the GBI construction. Construction materials for the new target launch pad and its associated support facilities would be transported to KLC via routes and in a manner similar to that utilized for transporting material for the GBI facilities. The transportation impacts from the construction of the target launch pad and its associated support facilities would be the same as for the GBI facilities.

**Operation**

**Pre-Launch Activities**

Implementation of Alternative 1 would result in single and dual target launches from KLC. Target missile components would be built in contractor facilities and delivered to KLC via air or boat for system assembly and checkout. Target missiles would not be shipped with initiators or other explosive devices. All missile components would be packaged in appropriately designed containers, labeled, and handled in accordance with applicable DOT regulations for the transport of hazardous materials. Trained personnel using only appropriately certified cranes and other materiel handling equipment would handle missile components and handling equipment in accordance with approved SOPs. There would be up to five target launches per year. As stated in section 4.1.11.2.1, Kodiak Island is one of the leading shipping ports in southwest Alaska and, as a commercial service facility, is equipped to accommodate this type of cargo and frequency of shipping; thus, there would be no impacts to transportation.

Once at Kodiak, the target missiles would likely be transported via roadways to KLC in the same manner as the GBIs. The impacts from the transfer of the target missiles to KLC would be similar to what is expected with the transfer of the GBIs, though GBIs could potentially utilize barge landings. Once at KLC, the missile components would be stored in a Missile Assembly Building until they are assembled for launch. The impact of the movement of the target missiles within KLC would be similar to what is expected with the GBIs.

A maximum of approximately 150 personnel would be required to support a dual target launch. They would travel to Kodiak via commercial airliner or the AMHS. It is assumed that approximately 50 personnel would be housed at the existing mancamp on Kodiak Ranch. If the additional mancamp is not constructed on KLC or the existing mancamp is not added on to, then it is conservatively estimated that the remaining 100 personnel would commute daily to KLC from accommodations in the surrounding areas and within the City of Kodiak during a peak month. This would add approximately 50 vehicles (assuming 2 persons per vehicle) to Rezanof Drive West each day during peak hours. Although the local road system could experience an increase in traffic, the increase would only minimally change the ADT on key local roads, and the impact on Level of Service would be negligible. Moreover, the proposed construction of the new mancamp on KLC property (see section 2.3.1.1) or expansion of the existing lodge located near KLC would reduce, if not preclude, this minor impact.

**Flight Activities**

When a target missile test flight is planned, the same type of clearance areas that were defined for the GBI in section 4.1.11.2.1 would be established and cleared for the target missile. These areas would be very similar or the same as the clearance areas for the GBI.
Post-Flight Activities
After a successful test, the clearance areas would be released, or allowed to be re-occupied. Test personnel would depart by commercial airliner or sea (via the AMHS). Thus, the impacts from post-flight target missile activities would be similar to those for the GBI.

4.1.11.2.3 In-Flight Interceptor Communication System Data Terminal

Construction
Implementation of Alternative 1 would result in the construction of an IDT on KLC. The IDT would be located near the Loran Station, the Oxidizer Storage facility, or near the entry road. The IDT would require approximately 0.8 hectare (2 acres) of land with an unobstructed line-of-sight. Construction equipment, material, and personnel for the IDT would arrive at KLC as part of the construction of the GBI and/or target construction efforts. Thus, there would be no additional impact to transportation from construction of an IDT.

One additional COMSATCOM system could be constructed at KLC as part of Alternative 1. Personnel numbers for its construction are included in the GBI construction numbers, and thus no impacts to transportation are expected from construction of this additional COMSATCOM.

Operation
The IDT sites would require three onsite support personnel when in operation. When not in operation, the onsite backup generators would be tested for approximately 45 minutes every 2 months. The personnel associated with the IDT would be part of the people required to support an interceptor launch and would not be an additional impact to transportation systems.

4.1.11.2.4 Sensors

Operation
Instrumentation associated with the launch of a target missile would include mobile telemetry sites, and a range control support equipment site. Representative telemetry sites are shown in figure 2.1.5-5. Telemetry is provided through a real-time data acquisition system. The mobile telemetry systems would consist of an 11-meter (31-foot) truck, two 5.4-meter (17.7-foot) antennas, and dual 10-kW generators. Range control support equipment would include a semitrailer van for the Flight Termination System, meteorological, transponder, control, communications, and timing systems. Target telemetry requirements include an up-range, mid-range, and down-range telemetry systems to support launches. One site could be located in a level gravel area 61 by 61 meters (200 by 200 feet) in the vicinity of the entry road and north of the maintenance building on KLC. Other up-range telemetry locations on Kodiak Island that may be used include Pasagshak and Pillar Mountain. Up-range telemetry locations that may be used in other parts of Alaska include Soldotna, Kenai, and Homer on the Kenai Peninsula, in south-central Alaska; Cordova, in southeast Alaska; and King Salmon and Adak Island in southwest Alaska. Examples of this equipment are shown in figure 2.1.5-4.

All of these systems are mobile and would be brought to the vicinity of the launch site approximately 1 to 2 weeks before the launch date. These systems would be transported to Kodiak by air or sea and then driven to KLC or other locations in Kodiak on the existing roads. Systems that would be located in Soldotna, Kenai, and Homer on the Kenai Peninsula would be
brought in by air, land, or sea and transported to their location by motor carrier. Systems that would be located in Cordova in southeast Alaska and King Salmon and Adak Island in southwest Alaska would only be brought in by air or sea and then driven to their location on the existing roads. Once onsite, they would remain in position until the launch event has been complete. In most cases the equipment would be removed within days after the launch. The personnel associated with the launch of a target missile would operate these systems. Since these systems encompass a small number of vehicles (seven), movement of these systems to KLC or other locations in south-central, southeastern, or southwestern Alaska would not have a measurable impact on the air, ocean, or ground transportation systems at any of these locations.

4.1.11.2.5 TPS-X

Construction
TPS-X components could be transported to the operation site from U.S. Government storage depots or contractor facilities by aircraft, sea vessels, or over land by trucks. Delivery would be conducted under routine procedures in accordance with applicable FAA and DOT safety standards to minimize any possible impacts to transportation. Site preparation would require construction of a gravel pad area of approximately 0.3 hectare (0.8 acre). The limited construction activities would have little to no effect on area transportation levels.

Operation
At KLC, the Prime Power Unit for the TPS-X would be a 1.5-MW generator that would provide power to the radar during testing. The generator is assumed to be in operation for 3 weeks (24 hours a day, 7 days a week) five times a year during launch activities. The total time of operation is estimated at a maximum of 2,520 hours per year. Operation of the Prime Power Unit would require refueling operations. The fuel tank would be filled from a fuel truck, as necessary. The limited trips required by the fuel truck would have no impact on current transportation systems.

4.1.11.2.6 Launch Complex Security

Security procedures would be established in accordance with AADC’s Interagency Land Management Agreement for property, which permits public exclusion during times of danger and assists in protecting structures. When interceptor testing occurs it would be on a periodic basis. It is assumed that testing would be on a campaign basis and the security for these tests would be on a similar basis. It is estimated that the potential security personnel would be on-site for approximately 5 weeks for each campaign. Implementation of this alternative would result in security personnel being brought to KLC during each campaign. The security personnel would travel to KLC via air or sea and would be housed onsite or offsite. Security vehicles would also be used. During the day, security vehicles would be on patrol, and at night additional vehicles would be used as needed. Since the additional security personnel would be working on site during much of the campaign, they would not measurably add to the ADT of the local roads. The addition of security vehicles would not measurably add to the ADT on KLC.

Up to three access control points would be required during a test campaign. One could be located at the entrance of KLC to record vehicles entering and leaving the site. The access control points would not disrupt the flow of traffic; however, they would be able to advise
motorists on the location of Launch Hazard Areas and minimize the potential for them to gain unauthorized access. Public access through KLC to Fossil Beach would be limited or denied only for each launch day. During the 5-week period building up to a launch, delays would be limited to clearance through security checkpoints. For the proposed five launches per year, the 5 days of closure would be less than 2 percent of the year.

4.1.11.3 Alternative 2

Alternative 2 would have GBIs launched from Vandenberg AFB instead of KLC. There would be no construction or operations related to GBI and its associated support equipment as well as an IDT. However the other components described in Alternative 1 would remain the same.

4.1.11.3.1 Target

The impacts to transportation from construction of a target launch pad and associated support facilities and the launch of single and dual targets from KLC would be similar to those discussed in section 4.1.11.2.2.

4.1.11.3.2 Sensors

The impacts to transportation from operation of target sensors on KLC or in other parts of southwestern Alaska would be similar to what was discussed in section 4.1.11.2.4.

4.1.11.4 Alternative 3

For the purposes of the discussion at KLC, the construction and flight impacts for Alternative 3 would be as described above for Alternative 1.

4.1.11.5 Cumulative Impacts

The KLC EA indicated no significant impacts to transportation from nine annual launches (Federal Aviation Administration, 1996). It is not likely that the Proposed Action of up to five launches (GBI and/or target) in conjunction with other currently planned or anticipated launches at KLC would exceed nine launches per year, the level of activity analyzed in the KLC EA, and therefore, no substantial cumulative impacts to transportation are expected. At this time, there are no ongoing or foreseeable future programs taking place in the ROI other than those discussed previously that would have an added impact on transportation. Plans on the part of the Alaska Department of Transportation to pave some additional 40 kilometers (25 miles) between the town of Kodiak and KLC would actually have a beneficial effect, reducing risk to both personnel and equipment required to travel this roadway. Paving activities are currently underway.

4.1.11.6 Mitigation Measures

No transportation mitigation measures are proposed for the GMD ETR activities at KLC.
4.1.12 UTILITIES—KODIAK LAUNCH COMPLEX

A project may have substantial effects on infrastructure and utilities if it increases demand in excess of the utility system’s capacity to the point that substantial expansion would be necessary. Environmental impacts could also result from system deterioration due to improper maintenance or extension of service beyond its useful life.

4.1.12.1 No Action Alternative

Missile Defense Agency

Under the MDA’s No Action Alternative, launches would continue to occur at KLC, although the GMD ETR would not be established and GBI and target launch scenarios would not be tested under more operationally realistic conditions. These launches could include missions in support of the GMD program. KLC would continue to operate as a licensed launch facility, and, as concluded in the KLC EA (Federal Aviation Administration, 1996), no impacts to area utilities would be anticipated.

Federal Aviation Administration

Under the FAA’s No Action Alternative, the launch site operator license for KLC would not be renewed and no launches would be allowed to occur from KLC. Therefore, there would be no impacts to utilities resources from launches at KLC.

There would be no impacts expected to utilities from the FAA’s No Action Alternative because there would be no additional launch events from KLC.

4.1.12.2 Alternative 1

4.1.12.2.1 Ground-Based Interceptors

Construction

Implementation of Alternative 1 would result in construction of several facilities as described in section 2.3.1.1. Kodiak Island and KLC have established air, ocean, and land transportation systems. Approximately 100 construction personnel would be brought to Kodiak Island during the course of construction of new facilities and modification of existing facilities.

Construction equipment and materials would also be shipped via sea or air to Kodiak Island. Once unloaded at Kodiak Island, construction equipment and materials would either be shipped by tractor-trailer transport or via one of the three potential beach landing sites to KLC. Access to KLC is via Rezanof Drive West.

In order to support construction and operations personnel, the creation of a new mancamp on KLC property (see section 2.3.1.1) has been proposed. Per table 2.3.1.2, this would house a maximum of 60 people. As an additional alternative, a similar-sized increase is proposed for the Narrow Cape Lodge, as well.
**Energy**
The addition of 100 construction personnel and related construction activities would not measurably increase the demand for electricity at KLC, although the housing of up to 60 personnel at the proposed mancamp or in the proposed expansion of the Narrow Cape Lodge would require the installation, or upgrading, of lines to tap into the current KLC electric system.

**Water**
The addition of 100 construction personnel and related construction activities would increase the demand for potable water. Given 189 liters (50 gallons) per day per worker, demand would be 18,927 liters (5,000 gallons) per day. This would be above the system capacity of 13,060 liters (3,450 gallons) per day. To allow for any additional demand, however, the utilization of portable drinking water systems would be necessary; this would include any potable water system required for the proposed mancamp.

Some water would be pumped from East Twin Lake for temporary use at the project’s cement batch plant and for emergency, fire-fighting purposes. Compared to the lake’s capacity (about 57 million liters [15 million gallons]) and average recharge rate (estimated to be 871 liters [230 gallons] per minute), this temporary use of water would represent a minor impact.

**Wastewater**
The addition of 100 construction personnel and their related construction activities would increase the demand on existing wastewater treatment services. Given 170 liters (45 gallons) per day per worker, wastewater production would be 17,034 liters (4,500 gallons) per day. This would be above the system capacity of 13,060 liters (3,450 gallons) per day. To allow for any additional demand, however, the utilization of portable septic/toilet systems would be necessary. This would include the installation of a septic/toilet system for the proposed mancamp, as necessary.

**Solid Waste**
Construction activities and 100 construction personnel would not increase the demand for solid waste disposal services beyond the existing capacity of 11.5 cubic meters (15 cubic yards) per month. Although construction of new facilities, such as the proposed mancamp, and modification of the existing Narrow Cape Lodge, would generate solid waste, this is not expected to exceed the existing capacity. Any increase over and above typical levels and capacity would be negotiated with and handled by the Kodiak Island Borough/Waste Management, Inc.

**Operation**

*Pre-Launch, Flight, and Post-Flight Activities*
Implementation of Alternative 1 would result in single and dual GBI launches from KLC. Interceptor missile boosters, payloads, and support equipment would be transported by air or ship from Government storage depots or contractor facilities to KLC. There would be up to five missile launches per year (target and interceptor). A maximum of approximately 235 personnel (contractor, military, and Government civilian) would be required to travel to KLC for a period of up to 2 months to support an interceptor launch. After an interceptor launch, the majority of these personnel would depart KLC and Kodiak.
As part of pre-launch and flight activities, a Launch Hazard Area would be established around the launch site in accord with the AADC Interagency Land Management Agreement has for the property, which allows public access restrictions in cases of public safety and to protect structures. The Launch Hazard Area would result in certain areas of KLC being cleared of personnel in the event of an accident during interceptor launch; however, establishing a Launch Hazard Area would not create an impact related to utility services.

**Energy.** An offsite commercial power supplier would be used to supply primary power to activities associated with missile flight tests, with a backup battery system and onsite backup diesel generators for emergency power. Generators for various GBI-related facilities would range in output from approximately 75 to 900 kW. Each generator would also have its own dedicated AST. Additionally, the new Missile Assembly Building would include wall mounted sodium-vapor lighting, aircraft obstruction lighting, and a 500-kW diesel generator. The integrated assemblies would be electronically tested. Therefore, compared to daily average demand for electricity at KLC of 825 kW, the total increase in demand for electricity would not exceed the existing capacity of 3,100 kW. No adverse impacts would be anticipated.

Additional electricity usage would occur as a result of up to a maximum 235 personnel residing offsite during the operational phase of the GBI. However, it is anticipated that the majority of the personnel would be staying at existing hotels and motels. This would create negligible additional demand on electricity services and would be within existing capacity. Upgrades to Narrow Cape Lodge or electric service for the proposed mancamp would of necessity provide the capacity for the electricity needs of up to 60 personnel.

**Water.** Domestic water usage represents the water consumed by the launch personnel in the ROI. Additional water usage would occur as a result of up to a maximum of 235 personnel at KLC to support a dual launch of the GBI.

Assuming an approximate average water requirement of 189 liters (50 gallons) per person per day, the water requirements for a typical dual launch flight test buildup are shown in table 4.1.12-1.

<table>
<thead>

<td>(3,750)</td>
<td>(7,500)</td>
</tr>
</tbody>
</table>

As shown in table 4.1.12-1, GMD requirements would exceed existing capacity of 13,060 liters (3,450 gallons) by as much as 31,419 liters (8,300 gallons). It is anticipated that additional
packaged potable water systems would be installed to meet the GMD requirements. The packaged system (well, pump, and AST) would be located within the construction footprint of the proposed GMD facilities. A new potable water system would be required for the proposed mancamp, if constructed. Permits would be obtained from the Alaska Department of Environmental Conservation for construction and use of the water supply systems, and such systems would comply with “new source” provisions as mandated by the Safe Drinking Water Act (see appendix B), as amended.

**Wastewater.** Assuming an approximate average of 170 liters (45 gallons) per person per day of wastewater production, the launch activities would generate wastewater at the rates shown in table 4.1.12-2.

As shown in table 4.1.12-2, GMD requirements would exceed existing design capacity of 13,060 liters (3,450 gallons) per day by as much as 26,970 liters (7,125 gallons). It is anticipated that new facility construction and additions to existing facilities would include additional wastewater treatment systems that, as with any additional potable water systems, would meet GMD requirements. Proposed construction of the new mancamp would also necessitate the installation of a wastewater system capable of accommodating up to 60 personnel. In keeping with KLC procedures, any septic systems would likely include a mounded absorption bed. Again, appropriate permits would be obtained where required.

**Solid Waste.** Municipal solid waste would be generated during the five GMD missile launches. However, the amount of waste is expected to be similar to previous missile launches and is not expected to exceed the existing quantity of 15 cubic yards (11.5 cubic meters), currently handled by Kodiak Island Borough/Waste Management, Inc. Were the amount of solid waste produced to increase over and above typical levels and capacity, however, this would be negotiated with and handled by the Kodiak Island Borough/Waste Management, Inc. Therefore, the total increase would not result in adverse impacts to existing services.
4.1.12.2 Target

Construction
Implementation of Alternative 1 would result in the construction of a new target launch pad and associated support facilities as described in section 2.3.1.1. The construction equipment and personnel associated with the target construction and associated support facilities would be similar to those used for the GBI facilities. The impacts from the construction of the target launch pad and its associated support facilities would be similar to the GBI construction impacts.

Energy
The impact to energy services from target facility construction would be similar to what would be expected for interceptor construction.

Water
The impact to potable water from target facility construction would be similar to what would be expected for interceptor construction.

Wastewater
The impact to wastewater from target facility construction would be similar to what would be expected for interceptor construction.

Solid Waste
The impact to solid waste from target facility construction would be similar to what would be expected for interceptor construction.

Operation
Pre-Launch, Flight, and Post-Flight Activities
Implementation of Alternative 1 would result in single and dual target launches from KLC. Target missile components would be built in contractor facilities and delivered to KLC via air or boat for system assembly and checkout. Trained personnel using only appropriately certified cranes and other materiel handling equipment would handle missile components and handling equipment in accordance with approved SOPs. There would be as many as five target launches per year.

The launch site, for target launches, would be occupied for approximately 3 months. A maximum of approximately 150 personnel (contractor, military, and government civilian) would be required to support a target launch.

Energy. An offsite commercial power supplier would be used to supply primary power to activities associated with the flight tests. Within the proposed Missile Service Structure, emergency power would be supplied from the Integration Processing Facility, and uninterrupted power supply batteries would serve critical loads. The Missile Assembly Building would include a 500-kW diesel generator. Additionally, both the Missile Assembly Building and Missile Service Structure would require wall mounted sodium-vapor lighting. Compared to the daily average
demand for electricity at KLC of 825 kW, the total increase in demand for electricity would not exceed the existing capacity of 3,100 kW. No adverse impacts would be anticipated.

**Water.** Domestic water usage represents the water consumed by the launch personnel in the ROI. Additional water usage would occur as a result of 150 personnel residing offsite during the operational phase of the target. However, it is anticipated that they would be staying at existing hotels/motels. This would not create additional demand on offsite water services, because they would not be exceeding the existing capacity of those facilities.

Table 4.1.12-1 shows water requirements for a typical target flight test buildup. As shown in the table, GMD requirements would eventually exceed existing capacity, but it is anticipated that additional packaged potable water systems would be installed to meet GMD requirements, thus negating the potential impact.

**Wastewater.** Assuming a proportional relationship between potable water consumption and wastewater treatment, the launch activities for targets would generate wastewater at the rates shown in table 4.1.12-2. Additionally, wastewater would be generated by the personnel residing offsite during the operational phase of the targets. However, it is anticipated that they would be staying at existing hotels/motels. Additional demand on wastewater treatment services would occur, but it would not exceed the existing capacity.

Table 4.1.12-2 shows wastewater requirements for a typical target flight test buildup. As shown in the table, GMD requirements would eventually exceed existing capacity, but it is anticipated that additional septic systems would be installed to meet GMD requirements, thus negating the potential impact.

**Solid Waste.** Municipal solid waste would be generated during the five GMD missile launches. However, the amount of waste is expected to be similar to previous missile launches and is not expected to exceed the existing quantity of 11.5 cubic meters (15 cubic yards), currently handled by Kodiak Island Borough/Waste Management, Inc. Were the amount of solid waste produced to increase over and above typical levels and capacity, however, this would be negotiated with and handled by the Kodiak Island Borough/Waste Management, Inc. Therefore, the total increase would not result in adverse impacts to existing services.

**4.1.12.2.3 In-Flight Interceptor Communication System Data Terminal Construction**

Implementation of Alternative 1 would result in the construction of an IDT on KLC. The IDT would be located near either the Loran Station, the Oxidizer Storage facility, or near the entry road. Construction equipment, material, and personnel would arrive at KLC as part of the construction of the GBI and/or target efforts. The different types of IDTs (i.e., re-locatable, mobile, and sea-based) do not require additional preparation (for construction and operation purposes) beyond what is required for land-based IDTs.

The IDT construction personnel and related construction equipment are included in the GBI construction. Potential impacts to energy, water, wastewater, and solid waste are included in section 4.1.12.2.
**Operation**

The IDT site would require three onsite support personnel when in operation. When not in operation, the onsite backup generators would be tested for approximately 45 minutes every 2 months. The personnel associated with the IDT would be part of the personnel (up to a maximum of 235) required to support an interceptor launch.

**4.1.12.2.4 Sensors**

**Construction**

These systems are mobile and would be brought to the vicinity of the launch site approximately 1 to 2 weeks before the launch site. No construction would be involved.

**Operation**

Implementation of Alternative 1 would include operation of mobile telemetry systems. The telemetry sites would be located in a level gravel area 61 by 61 meters (200 by 200 feet) in the vicinity of the #1 entry road and southwest of the Loran Station on KLC. Other up-range telemetry locations that may be used in other parts of Alaska include Soldotna, Kenai, Cordova, and Homer on the Kenai Peninsula in south-central Alaska and King Salmon and Adak Island in southwest Alaska.

These systems would be transported to Kodiak. Once onsite, they would remain in position until the launch event has been complete. In most cases the equipment would be removed within days after the launch. The personnel associated with the launch of a target missile would operate these systems.

**Energy**

The mobile telemetry systems would include dual 10-kW generators. Operation of the sensors would not require any additional electricity. Current capacities would not be exceeded. No adverse impacts would be anticipated.

**Water**

Domestic water usage represents the water consumed by the operation personnel in the ROI. In this case, the target missile launch personnel would operate these systems; therefore, no additional personnel over the 150 personnel already involved in target operations would be needed to operate the sensors.

**Wastewater**

The target missile launch personnel would operate these systems; therefore, no additional personnel over the 150 personnel already involved in target operations would be needed to operate the sensors.

**Solid Waste**

The target missile launch personnel would operate these systems; therefore, no additional personnel over the 150 personnel already involved in target operations would be needed to operate the sensors.
4.1.12.2.5 TPS-X

Construction

Installation of the TPS-X radar would require disturbance to 0.3 hectare (0.8 acre) of land on KLC for placement of a concrete pad. Potential impacts to energy, water, wastewater, and solid waste are included in section 4.1.12.2.

Operation

At KLC, the Prime Power Unit for the TPS-X would be a 1.5-MW generator that would provide power to the radar during testing. The generator is assumed to be in operation for 3 weeks (24 hours a day, 7 days a week) five times a year during launch activities. The total time of operation is estimated at a maximum of 2,520 hours per year. Operation of the Prime Power Unit would require refueling operations, the fuel tank being filled from a fuel truck, as necessary. Such operations are routine and would have no impact on area utilities.

4.1.12.3 Alternative 2

Under Alternative 2, GBIs would be launched from Vandenberg AFB instead of KLC. Thus, there would be no construction or operations related to GBI and its associated support. However, the other components described in Alternative 1 would remain the same, and the impacts would be the same.

4.1.12.3.1 Target

The impacts to utilities (energy, water, wastewater, and solid waste) from construction of a target launch pad and associated support facilities and the launch of single and dual targets from KLC would be similar to what was discussed in section 4.1.12.2.2.

4.1.12.3.2 Sensors

The impacts to utilities (energy, water, wastewater, and solid waste) from operation of target sensors on KLC or other parts of southwestern Alaska would be similar to that discussed in section 4.1.12.2.4.

4.1.12.4 Alternative 3

Implementation of Alternative 3 would combine activities proposed for Alternative 1 and Alternative 2 and would include GBI launches from both KLC and Vandenberg AFB and construction of the required facilities. Therefore, the impacts to utilities (energy, water, wastewater, and solid waste) from Alternative 3 would be similar to those found under Alternative 1.

4.1.12.5 Cumulative Impacts

The KLC EA indicated no significant impacts to utility systems from nine annual launches (Federal Aviation Administration, 1996). Although direct impacts from the Proposed Action on potable water and wastewater would eventually exceed current capacity, these impacts would
be localized and this increased demand would be circumvented by the addition of potable water and septic systems to handle any increase over current capacity. It is not likely that the Proposed Action of up to five launches (GBI and/or target) in conjunction with other currently planned or anticipated launches at KLC would exceed nine launches per year; the level of activity analyzed in the KLC EA, and would not result in any cumulative impacts to KLC utilities. In addition, there are no other ongoing or foreseeable future programs taking place in the ROI that would result in cumulative impacts.

4.1.12.6 Mitigation Measures

Direct impacts to water and wastewater demand and capacity, as previously addressed, would be met by the addition of new potable water and septic systems. No significant impacts to utilities systems would be anticipated and additional mitigation measures would not be required or proposed.

4.1.13 VISUAL AND AESTHETIC RESOURCES—KODIAK LAUNCH COMPLEX

4.1.13.1 No Action Alternative

Missile Defense Agency

Under the MDA’s No Action Alternative, launches would continue to occur from KLC but the GMD ETR would not be established and interceptor and target launch scenarios would not be tested under more operationally realistic conditions. There would be no alteration of the existing visual setting at KLC and the adjacent area. No significant impacts to visual and aesthetic resources would occur, and no mitigation measures are proposed.

Federal Aviation Administration

Under the FAA’s No Action Alternative, the launch site operator license for KLC would not be renewed and no launches would be allowed to occur from KLC. Therefore, there would be no impacts to visual and aesthetic resources from launches at KLC.

4.1.13.2 Alternative 1

Visual impacts may be associated with changes in either the built or natural environment and can be short-term or long-term. The presence of heavy machinery during construction of the project is considered a short-term visual impact. Large trucks, cranes, and other construction equipment would be visible within the construction zone and in surrounding areas only during the construction phase. Long-term visual changes are associated with altering the existing visual environment by constructing buildings, including one with a very high vertical profile. The focus of this analysis is those long-term physical changes that are permanent in nature.

The construction and operation of the proposed GMD facilities at KLC would affect the visual resources of Narrow Cape by introducing new structures into a relatively isolated area that has both natural and man-made elements. The proposed KLC infrastructure for launching targets and interceptors would involve the construction of new structures and facilities to support the GMD program at various locations within the launch complex. Proposed new facilities are described in section 2.3.1.1.
Construction of these facilities would place additional man-made, mostly pre-engineered buildings that are color compatible to the existing facilities into an area that, although regionally scenic, has a somewhat disturbed local viewscape. Several of the proposed structures, including the Missile Assembly Building (18 meters [60 feet] high) and the Movable Missile Building (33.5 meters [110 feet] high), would change the view horizon. Other proposed buildings, such as the IDT, would have a noticeable horizontal presence. There is also the potential for impacts to visual resources due to nighttime lighting, particularly during construction.

In an effort to determine the existing visual quality, the following method was modified from *Landscape Aesthetics: A Handbook for Scenery Management* (U.S. Department of Agriculture, U.S. Forest Service, 1995). The handbook outlines ways to measure individual aspects of visual resources and then rate the scenic value class of each of the locations. The following criteria were used to determine the scenic value class for the Proposed Action location at KLC: scenic attractiveness, viewer concern, and distance zones. Scenic attractiveness is the measure of scenic quality based on human perceptions of inherent beauty of the forms, colors, textures, and visual composition of an individual landscape. Viewer concern can be defined as the level of scenic importance based on expressed human concern for the scenic quality of land areas viewed. The distance zone is a principal indicator of scenic importance based on the distance an area can be seen by observers and the degree of visible detail within that zone. In addition, scenic integrity is included to determine the current level of modification to an area. A description of the scenic value rating criteria and scenic attractiveness can be found in appendix B.

**Scenic Attractiveness**
The area encompassing KLC would be considered as having a “typical” (B) level of scenic attractiveness and is very similar to other regions of the island.

**Concern Level**
Potential viewers of the Proposed Action at KLC include hikers and other recreational users and would have a high (Level 1) level of concern for the scenic quality of the ROI.

**Distance Zone**
Viewers would be able to observe the Proposed Action over a wide variety of distances including within the foreground (FG) and mid-ground (MG) for the construction and within the background (BG) for launches.

**Scenic Value Class**
The scenic value class for KLC as determined from the Scenic Value Class table 4.1.13-1 is 1 to 2 and equates to a high public value scenic class.

**Scenic Integrity**
KLC has sporadically been altered and would be considered to have a moderate scenic integrity.
Table 4.1.13-1: Scenic Value Class Determined for KLC

<table>
<thead>
<tr>
<th>Scenic Attractiveness</th>
<th>Distance Zones and Concern Levels</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>FG1</td>
</tr>
<tr>
<td>A</td>
<td>1</td>
</tr>
<tr>
<td>B</td>
<td>1</td>
</tr>
<tr>
<td>C</td>
<td>1</td>
</tr>
</tbody>
</table>

Scenic Attractiveness
A – Distinctive, B – Typical, C – Indistinctive
Distance zone and Concern Level
FG1 – Foreground with a high level of concern
MG1 – Mid-ground with a high level of concern
BG1 – Background with a high level of sensitivity
FG2 – Foreground with a moderate level of sensitivity
MG2 – Mid-ground with a moderate level of sensitivity
BG2 – Background with a moderate level of sensitivity
FG3 – Foreground with a low level of sensitivity
MG3 – Mid-ground with a low level of sensitivity
BG3 – Background with a low level of sensitivity

Scenic Value Class
1-2: High public value.
3-5: Moderate public value.
6-7: Low public value.

There are no residences in the immediate vicinity of KLC, and the nearest park is approximately 10 kilometers (6 miles) away. The existing AADC facilities along with the U.S. Coast Guard’s 190-meter-high (625-foot-high) Loran-C navigation transmitter tower and associated white-colored buildings already have a visual presence that alters the natural viewscape of the area. Although the Narrow Cape area is being developed, there is the potential that some sensitive viewers would be affected, particularly hikers, fishermen, and other recreational users; even though the amount of concerned viewers would be somewhat limited, there is a potential for adverse affects to visual resources.

4.1.13.3 Alternative 2
The construction and operation of target facilities at KLC for Alternative 2 would be the same as that for Alternative 1. An IDT and GBI related facilities would not be constructed at KLC. As discussed under Alternative 1, the Proposed Action would not have a significant impact on aesthetic or visual resources.

4.1.13.4 Alternative 3
Alternative 3 would be identical to Alternative 1 at KLC. Because Alternative 1 includes GBIs, targets, and all associated facilities, the construction and flight impacts to visual and aesthetics from Alternative 3 would be as described for Alternative 1.
4.1.13.5 Cumulative Impacts
Although construction of new facilities could potentially double the amount of development within and the area and would result in visual cumulative impacts, the area proposed for development is already designated as a commercial launch facility.

4.1.13.6 Mitigation Measures
No visual resources mitigation measures are proposed for the GMD ETR activities at KLC.

4.1.14 WATER RESOURCES—KODIAK LAUNCH COMPLEX
This section addresses potential impacts to surface water and groundwater resources. Both freshwater and marine surface waters are covered. Potential changes in the availability of water supplies for consumptive purposes are also addressed. None of the action alternatives would involve the construction of new facilities in a floodplain; therefore, floodplain-related impacts are not addressed. Wetland-related impacts are addressed in section 4.1.3.

A proposed alternative would cause an adverse and significant impact on water resources if it would cause:

- A violation of applicable state or federal water quality standards, or inconsistencies with related stormwater pollution prevention plans, or other applicable water quality-related plans, policies, or permit conditions
- Major changes in existing drainage and runoff patterns that alter the course of existing waterways or exceed the capacity of existing stormwater drainage systems
- An increase in the use of consumptive water supplies to the point where the capacity of existing supply systems would not be adequate and new water supply sources would be needed
- Or if it would otherwise substantially degrade water quality

Best Management Practices and other SOPs would be used during construction and operational activities to minimize erosion and other types of impacts that could reduce the quality of affected water resources. Water quality-related SOPs that apply to each of the action alternatives are listed below. Mitigation commitments from previous environmental studies that are unique to a site or activity are described under the related alternative.

- Site preparation—vegetation preservation and protection, topsoil preservation, dust control, and temporary gravel construction entrance and exit
- Surface stabilization—temporary and permanent seeding and use of mulches and fabric and gravel blankets
- Runoff control and conveyance measures—installation of diversions, dikes, grassed waterways, and temporary slope drains
- Sediment barriers—straw bale and rock barriers, sediment fences
- Sediment traps and basins
- Stream protection—temporary stream crossings and streambank stabilization
- Protection of soil and fill storage piles

SOPs related to the handling, disposal, recycling, and other use of hazardous materials and wastes would be followed, including spill prevention, containment, and control measures while transporting equipment and materials. Other water quality-related SOPs to be followed include the use of portable toilets and waste disposal practices during construction, rapid response, control and cleanup activities in the event of unplanned spills or accidents, and worker education and training programs.

4.1.14.1 No Action Alternative

Missile Defense Agency

Under the MDA’s No Action Alternative, launches would continue to occur from KLC but the GMD ETR would not be established and interceptor and target launch scenarios would not be tested under more operationally realistic conditions. Table 4.1.1-1 summarizes the propellant information associated with these launches. The primary exhaust products from launches at KLC to date include hydrogen chloride, carbon monoxide, nitrogen oxide and aluminum oxide. These products would continue to be released and dispersed over large areas, with some of the emissions landing on surface water resources, or soil where they may enter the area’s water resources at a later time. The existing water quality monitoring required by KLC’s 401 Water Quality Assurance Permit (pH, perchlorates, and total aluminum) from the Alaska Department of Environmental Conservation, and the implementation of related components of the KLC NRMP would continue under all of the alternatives assessed in this EIS, including the MDA’s No Action Alternative. Water quality monitoring and the KLC NRMP are described further in section 4.1.14.2.

Federal Aviation Administration

Under the FAA’s No Action Alternative, the launch site operator license for KLC would not be renewed and no launches would be allowed to occur from KLC. Therefore, there would be no impacts to water resources from launches at KLC.

4.1.14.2 Alternative 1

4.1.14.2.1 Ground-Based Interceptors

Construction

Construction of the new GBI-related facilities as described in section 2.3.1.1 has the potential to disturb approximately 14.4 hectares (35.5 acres) and cause adverse water quality impacts to nearby surface waters. These construction-related impacts could include an increase in the discharge of sediments and turbidity levels in receiving waters. Construction crews may accidentally spill some of the material used during construction procedures or by construction vehicles, including fuel, cement, paint, anti-freeze, oil, etc. None of these construction-related impacts are expected to be significant. The SOPs discussed in the beginning of section 4.1.14 and the commitments included in the KLC NRMP (described in the next paragraph) are all expected to minimize the magnitude of adverse water quality impacts. Only minor erosion and turbidity impacts, and insignificant and accidental spillage of petroleum products and other construction materials are expected.
The KLC NRMP commitments include such measures as collecting and disposing of sewage offsite, monitoring of soil conditions, periodic inspection by a designee of AADC to ensure erosion and sediment control structures are working properly, hazardous waste management measures and offsite disposal, post-launch monitoring and revegetation of areas around launch sites if needed (Alaska Aerospace Development Corporation, 1998). All of the SOPs and water quality-related elements of the KLC NRMP would be reviewed with Alaska Department of Environmental Conservation staff during consultations for the project’s required 401 Water Quality Assurance Permit. A related Stormwater Pollution Prevention Plan would be prepared before construction for the Alaska Department of Environmental Conservation (or the existing Plan would be amended) and would specify all of the measures to be used during construction to minimize and avoid adverse water quality impacts.

Potable water would be transported to facility sites during construction. Some water would be pumped from East Twin Lake for temporary use at the project’s cement batch plant and for emergency, fire-fighting purposes. Compared to the lake’s capacity (about 57 million liters [15 million gallons]) and average recharge rate (estimated to be 871 liters [230 gallons] per minute), this temporary use of water would represent a minor impact.

**Operation**

*Pre-Launch, Flight and Post-Flight Activities*

This section addresses potential impacts that could occur during any of the operational phases. The next section describes potential impacts unique to the flight operational phase.

Hazardous materials would be used during operational phases and such use has the potential to cause adverse and significant water quality impacts. As described in section 3.1.6, numerous SOPs, a spill prevention plan, and emergency response plan are currently in place and being used at KLC and would continue to be used under this alternative. These measures would minimize the risk of accidental spills to an acceptable level and significant and related water quality impacts would not occur.

The leaching of domestic sewage wastewater from septic tanks would occur as designed during operations.

Potable water used during operations would come in part from the existing water supply system. As noted in section 4.1.12.2, insufficient capacity exists in the current system to handle the increases in demand associated with this alternative. Therefore, new water supply sources would be needed. It is anticipated that packaged potable water systems, similar to the existing water systems, would be installed to meet the GMD requirements. The packaged system (well, pump, and AST) would be located within the construction footprint of the proposed GMD facilities. Permits would be obtained from the Alaska Department of Environmental Conservation for construction and use of the water supply systems.

*Flight Activities*

The missiles launched from KLC under this alternative would disperse certain exhaust emission products over a large area. These emissions would not cause a significant water quality impact. The primary emission products of concern from a water quality-standpoint are hydrogen chloride, which combines with water or water vapor in the atmosphere and forms hydrochloric
acid and aluminum oxide. Table 4.1.1-8 shows more information regarding the amounts and type of emissions from launched rockets. In any one area of the ROI, only small amounts of these combustion products would be present. For example, the 1996 KLC EA estimated the launching of an Athena-2 rocket would result in a maximum deposition of 0.427 grams of hydrogen chloride per square meter of surface area over a 10-square-kilometer (4-square-mile) area (Federal Aviation Administration, 1996). These small amounts of hydrogen chloride would be transitory given the area’s hydrologic characteristics and climate. The contaminants would be quickly washed out of the area’s relatively short and steep drainages during and after frequent precipitation events.

Aluminum oxide also would be emitted during missile launches and deposited in ROI surface waters. However, aluminum oxide is only a hazard to aquatic life in acidic environments when it dissolves into a free aluminum cation (Federal Aviation Administration, 1996). Aluminum oxide should not dissolve in water with pH levels between 5 and 9.5 because aluminum hydroxide, a much more soluble compound than aluminum oxide, is insoluble between pH levels 5 and 9.5. As summarized in Summary Findings of Environmental Monitoring Studies for the Kodiak Launch Complex 1998–2001 (Alaska Aerospace Development Administration, 2002b), water quality sampling and analysis indicate there have been no discernable effects on water chemistry from KLC launches to date. Water quality was sampled before and after KLC launches, including pH level, total aluminum, and perchlorate concentration. Samples were taken at various locations as shown in figure 3.1.14-1. The levels for pH, measured in streams 2, 4, 7b, and 8, ranged from 6.1 to 7.8. Table 4.1.14-1 provides results of the sampling for total aluminum and perchlorate concentration.

As shown in the table, total recoverable aluminum was detected in very low concentrations in the three water bodies sampled, but these did not exceed levels considered to be toxic to aquatic life and were comparable to values found elsewhere in Alaska. Although not shown, there was no associated decrease in pH to warrant concern from aluminum toxicity. As a result of the monitoring, the Environmental and Natural Resources Institute recommended long-term pH monitoring. AADC is conducting ongoing monitoring for pH, perchlorates (EPA method 314.0 for water), and total aluminum at an observation well adjacent to the existing Launch Pad 1. Results of the monitoring are provided to the Alaska Department of Environmental Conservation.

Measurable or significant impacts to ocean water quality from launches are not expected. Spent rocket cases are composed of inert materials and do not represent a threat to water quality once their propellants are burned (Federal Aviation Administration, 1996). Early termination of a flight would lead to some amount of propellant reaching the ground, surface waters, or the ocean. The propellant is an inert, solid rubber material impregnated with ammonium perchlorate salt. A recent study conducted for the U.S. Air Force (Lang, et al., 2001) measured the amount of perchlorate lost from solid propellant samples immersed in fresh and salt water. From the measurement of the concentration of the perchlorate ion in solution, the mass fraction loss of the propellant sample due to perchlorate leaching was calculated. Table 4.1.14-2 presents the results.

The same report provided an average water temperature at a buoy in Alaska as 8.3°C (47°F). As shown in the table, it would take approximately 18 years for 90 percent of the perchlorate to leach out of solid propellant that lands in the ocean. For fresh water areas the temperature would be higher, and it would take about 1 year for 90 percent of the perchlorate to leach out. Even at this higher rate the perchlorate would be expected to be diluted as it mixes with the surrounding water. For an accident involving fresh water areas, larger pieces of propellant would be recovered, further minimizing the potential for perchlorate contamination.

In the unlikely event of an on-pad fire or catastrophic missile failure over land, most or all of the solid propellant fuel would likely burn up before being extinguished. Any remaining fuel would be collected and disposed of as a hazardous waste. The total quantities of hydrogen chloride and aluminum oxide released in an on-pad failure of a GBI would be equivalent to that released during a nominal launch of an Athena-2. Therefore, an on-pad failure is not expected to result in significant ground deposition of either pollutant.

4.1.14.2.2 Targets

Construction

Construction of the new target facilities has the potential to disturb approximately 10.5 hectares (26.0 acres) and cause the same type of construction-related water quality impacts described in section 4.1.14.2.1. Like the GBI-related construction, the SOPs and KLC NRMP commitments discussed in section 4.1.14.2.1 would prevent the target facility-related construction impacts from being significant.
Operation

Pre-Launch, Flight and Post-Flight Activities

The types of operations-related water resource impacts discussed in section 4.1.14.2.1 and common to pre-launch, flight, and post-launch activities would also be associated with the target launches included in this alternative. These impacts would be minor for the same reasons described in section 4.1.14.2.1.

Flight Activities

Target launches under this alternative would be similar to existing target launches at KLC. Table 4.1.1-13 in section 4.1.1.2.2 shows the expected emissions associated with these launches. While some deposition of these emissions would occur on freshwater and ocean surface waters, these depositions would not be a significant impact for the reasons described in section 4.1.14.2.1.

In the event of an on-pad fire or terminated launch, the Peacekeeper Target could potentially release 76,848 kilograms (169,420 pounds) of solid propellant, and 1968 liters (520 gallons) of liquid fuel. As discussed in section 4.1.5.2.1, most of the solid propellant would be expected to burn upon impact with the ground. Unburned components of the fuel would be removed and treated as hazardous waste. The total quantity of aluminum oxide and hydrogen chloride released in an on-pad failure of a Peacekeeper target would be approximately 26,900 kilograms (59,300 pounds) and 12,300 kilograms (27,100 pounds) respectively. This would be equivalent to that released during 3 nominal launches of an Athena-2 missile. As discussed in section 4.1.1.2.2, the airborne concentrations of the pollutants would be higher than during a nominal launch, but would return to ambient levels within several hours. Modeling results from the testing of much larger Advanced Solid Rocket Motor program vehicles, which output 196,357 kilograms (432,885 pounds) of aluminum oxide and 115,572 kilograms (254,789 pounds) of hydrogen chloride concluded that there would be no significant impacts to surface water from aluminum oxide and hydrogen chloride deposition (National Aeronautics and Space Administration, 1990). Most of the aluminum oxide would be suspended in the air and dispersed over extremely large areas, and the amount of aluminum oxide deposited in surface waters would have not significant impacts. The hydrogen chloride, under the most conservative rain conditions, would be buffered by the water and would not significantly change the pH of the water (National Aeronautics and Space Administration, 1990). The effects of hydrogen chloride deposition into surface waters are dependent upon the pH and buffering capability of the water. The buffering capability is a result of the degree of alkalinity in the water. Measurements of alkalinity are expressed in milligrams of calcium carbonate per liter of water. The higher the alkalinity, the greater the buffering capability. Alkalinity values from the Advanced Solid Rocket Motor program ranged from 5 milligrams calcium carbonate equivalent per liter to 124 milligrams calcium carbonate equivalent per liter with a mean value of 25 milligrams calcium carbonate equivalent per liter (National Aeronautics and Space Administration, 1990). The alkalinity values of surface water within the ROI as listed in table 3.1.14-1 have an average value of 19 milligrams calcium carbonate equivalent per liter and would have a similar buffering capability. Deposition of hydrogen chloride would result in a not significant impact to surface water due to the buffering capability of the water and the relatively small amount of hydrogen chloride deposited.

In the highly unlikely case of an on-pad accident, the liquid fuel (hydrazine) from the fourth stage of the Peacekeeper target is heavier than air and, if not oxidized when airborne, would react and/or possibly ignite with the porous earth or would form dimethylamine and oxides of nitrogen.
All of these substances are soluble in water. Airborne nitrogen dioxide would return to earth as dilute nitric acid rains in precipitation events. (U.S. Army Space and Strategic Defense Command, 1995)

4.1.14.2.3 In-Flight Interceptor Communication System Data Terminal

Construction
Construction of the IDT, COMSATCOM, and connecting roads would cause a minor increase in the discharge of sediments to receiving waters. These waters may also receive some construction-related pollutants, especially if materials are accidentally spilled by construction crews. However, the area to be disturbed is relatively small (approximately 5.9 hectares [14.6 acres]), and the SOPs and KLC NRMP-related commitments described in section 4.1.14.2.1 would prevent these impacts from being significant.

Existing water utilities are sufficient to handle the minor increase in demand for potable water during construction. Therefore, new water sources would not be needed.

Operation
Operation of the IDT and COMSATCOMs would have negligible effects on water quality. Potable water demands associated with the operation of these facilities can easily be served by existing infrastructure.

4.1.14.2.4 Sensors

Construction
The construction of two gravel pads for mobile telemetry would have very little impact on water quality. Minor amounts of sediment may enter nearby drainages, but these impacts would be minor.

Operation
Negligible amounts of motor oil or other automotive-related products may enter nearby drainages as vehicles associated with mobile units use the gravel pads and related roads. These impacts would be minor.

4.1.14.2.5 TPS-X Radar

The TPS-X construction, operation requirements, and potential impacts to water resources would be similar to that described above for the IDT. The alternative locations are the same, and the potential impacts would be similar.

4.1.14.3 Alternative 2

4.1.14.3.1 Targets

The impacts of target-related construction and operational activities on water resources under this alternative would be very similar to those described for Alternative 1 in section 4.1.14.2.2.
The total acreage disturbed would be the same as for Alternative 1. None of the impacts would be significant.

4.1.14.3.2 Sensors

The impacts of sensor-related activities at KLC on water resources under this alternative would be the same as those described for Alternative 1 in section 4.1.14.2.4.

4.1.14.4 Alternative 3

Because Alternative 1 includes GBIs, targets, and all associated facilities, the construction and flight impacts to water resources from Alternative 3 would be as described for Alternative 1.

4.1.14.5 Cumulative Impacts

The Proposed Action and its alternatives are not expected to combine with related past, ongoing, or reasonably foreseeable actions to cause substantial cumulative impacts to water resources. Existing missile launches at KLC combined with the launches included in the Proposed Action would result in minor, short-term adverse water quality impacts in those areas where rocket emissions are deposited. For the same reasons described in section 4.1.14.2.1, such impacts would not be significant. Past construction at KLC combined with the new construction included in the Proposed Action and its alternatives would cause cumulative, but minor and temporary, increases in stormwater runoff and related discharges of sediments in affected drainages. These insignificant impacts have and would occur in drainages near paved areas or areas that are proposed to be paved. Such impacts have been and would continue to be minimized by construction SOPs and other commitments included in the related Stormwater Pollution Prevention Plan. Additional ongoing or foreseeable actions that would contribute to cumulative impacts to water resources have not been identified.

4.1.14.6 Mitigation

No water resources mitigation measures are proposed for the GMD ETR activities at KLC.

4.1.15 SUBSISTENCE—KODIAK LAUNCH COMPLEX

The subsistence resources analytical approach involved evaluating the potential impacts of the Proposed Action and alternatives, such as construction, site preparation activities, use of existing and new sensors, and missile launches, on potential subsistence harvest access within the ROI. Several documents were analyzed to determine the effects to subsistence caused by the program.

4.1.15.1 No Action Alternative

Missile Defense Agency

Under the MDA’s No Action Alternative, launches would continue to occur from KLC, but the GMD ETR would not be established and interceptor and target launch scenarios would not be tested under more operationally realistic conditions. Native Alaskans would continue to be allowed access to KLC for subsistence harvests between launches. According to the KLC EA,
to ensure public safety, access to some areas would be prohibited for a day up to nine times per year before a launch, which would result in minimal impacts to subsistence harvesting.

**Federal Aviation Administration**

Under the FAA’s No Action Alternative, the launch site operator license for KLC would not be renewed and no launches would be allowed to occur from KLC. Therefore, there would be no closure of areas to subsistence harvesting during launches at KLC.

**4.1.15.2 Alternative 1**

The Proposed Action would require construction at KLC as described in section 2.3.1.1. New construction would occur mainly in upland areas, which would not impact the subsistence harvest of marine species.

Limitation of access for Alternative 1 would be mainly because of safety and security precautions taken before and during a launch to ensure that no unauthorized people are within the Ground Hazard Area around the launch site. Access would be limited for 1 day for each GBI or target missile launch, approximately 5 days per year for GMD launches. Since the Narrow Cape area hosts only a limited amount of subsistence harvesting and the entire coast from Pasagshak Bay to the southern end of the island is a harvesting area, temporarily restricting public access during GMD ETR pre-launch and launch activities as part of the activities would not be significant.

**4.1.15.3 Alternative 2**

The Proposed Actions at KLC under Alternative 2 would be identical to those described under Alternative 1, except GBI launches would occur from Vandenberg AFB and RTS instead of KLC and RTS. Potential restricted access to KLC would be as described for Alternative 1.

**4.1.15.4 Alternative 3**

Alternative 3 would be identical to Alternative 1 at KLC and would include GBI launches from both KLC and Vandenberg AFB, and construction of the required support facilities. Because Alternative 1 includes GBIs, targets, and all associated facilities, the construction and flight impacts to from Alternative 3 would be as described for Alternative 1.

**4.1.15.5 Cumulative Impacts**

The KLC EA indicated no cumulative impact to subsistence harvest for nine annual launches (Federal Aviation Administration, 1996). It is not likely that the Proposed Action of up to five launches (GBI and/or target) in conjunction with other currently planned or anticipated launches at KLC would exceed nine launches per year, the level of activity analyzed in the KLC EA. No other activities have been identified that when combined with any of the alternatives would contribute to cumulative impacts to subsistence on or near KLC.

**4.1.15.6 Mitigation Measures**

No subsistence mitigation measures are proposed for the GMD ETR activities at KLC.
4.2 MIDWAY

Although Midway was an alternative site in the Draft EIS, MDA has determined that it is no longer a reasonable alternative and would not be a proposed site for ETR activities. The IDT on-board the SBX would perform the function that had been planned for Midway. The discussion of Midway has been retained in the Final EIS, however, in order to preserve the work that has already been performed. The Proposed Action in the mid-Pacific is the same for all three alternatives; therefore, the environmental consequences would be the same for all. Midway would continue to serve as a National Wildlife Refuge under direction of the USFWS for both the No Action Alternative and the Proposed Action alternatives.

4.2.1 AIR QUALITY—MIDWAY

4.2.1.1 No Action Alternative

Under the No Action Alternative, IDT and COMSATCOM facilities would not be constructed for the GMD ETR, and Midway would continue to serve as a National Wildlife Refuge under direction of the USFWS. There would be no impact to air quality.

4.2.1.2 Alternatives 1, 2, and 3

4.2.1.2.1 In-Flight Interceptor Communication System Data Terminal

Construction

Construction activities would include construction of one IDT, COMSATCOM, and fenced areas surrounding the facilities at one of the two proposed sites. Both sites are located on existing paved areas; therefore, ground disturbance would be kept to a minimum with only minimal emissions generated during construction.

Construction would be conducted in accordance with applicable federal and state regulations and permits. Construction air quality impacts would be both temporary and localized in nature. Once construction is completed, air quality would return to its former level.

Operation

Operation of the IDT and COMSATCOM would not result in long term or permanent impacts to the regional air quality. Power would be provided by a commercial source with a 275-kW backup generator. Along with the generator, an external aboveground 3,785-liter (1,000-gallon) fuel tank would be provided. Table 4.2.1-1 lists potential emissions for the generator if it is run up to 250 hours a year for weekly testing and power outages. These levels would not exceed existing standards.
Table 4.2.1-1: Potential Generator Emissions for IDT and COMSATCOM Facilities at Midway

</tr>
</tbody>
</table>

4.2.1.2.2 Sensors

Construction

Mobile telemetry would utilize an existing gravel pad or paved area and result in no new construction; therefore, there would be no air quality impacts from construction.

Operation

Minor air quality impacts are expected during the operation of the mobile telemetry at Midway. Power would be provided by a 10-kW generator, which is assumed to be in operation for 3 weeks (24 hours a day, 7 days a week) five times a year during test activities. The total operating time is estimated at a maximum of 2,520 hours per year. Table 4.2.1-2 lists the possible emissions that could be generated and are anticipated to remain within existing air standards.

</tbody>
</table>

4.2.1.3 Cumulative Impacts

The limited construction and operation of the IDT and COMSATCOM, when combined with current activities on Midway, are not expected to result in significant cumulative air quality impacts.

4.2.1.4 Mitigation Measures

No air quality mitigation measures are proposed for the GMD ETR activities at Midway.
4.2.2 BIOLOGICAL RESOURCES—MIDWAY

The Proposed Action in the mid-Pacific is the same for all three alternatives; therefore, the environmental consequences would be the same for all.

4.2.2.1 No Action Alternative

Under the No Action Alternative, IDT and COMSATCOM facilities would not be constructed for the GMD ETR and Midway would continue to serve as a National Wildlife Refuge under direction of the USFWS. There would be no impact to biological resources.

4.2.2.2 Alternatives 1, 2, and 3

The Proposed Action would require construction and operation of an IDT and two COMSATCOMs, and operation of mobile telemetry. Installation and operation of the IDT and COMSATCOMs, as well as operation of the sea-based IDT, would comply with all applicable regulations, such as the Plant Protection Act of 2000 (7 USC 7701, et. seq.); Executive Order 13112, Invasive Species (3 February 1999); and the National Invasive Species Act of 1996 (16 USC 4701, et seq.; see appendix B). The Proposed Action would follow all applicable procedures in place at Midway to prevent the introduction of alien nuisance species, such as removing visible mud, plant, fish, or animals from equipment before transporting it to Midway. Midway would continue to serve as a National Wildlife Refuge under direction of the USFWS.

GMD ETR program personnel would remove all mobile equipment/assets brought to the installation at the conclusion of its testing activities. Transportation for removal of equipment would be the same as when it was brought onto the island. These activities would result in impacts similar to, but less than, those caused by site preparation. Specific restoration actions, if necessary, would be determined on a case-by-case basis.

Site Preparation Activities

Vegetation

The IDT on Midway would require construction of an IDT on an existing paved area or pad within a fenced area. The fencing would be installed in the smallest area practicable, no more than 2 hectares (5 acres). The IDT would be located in previously disturbed areas to further minimize impacts to vegetation and would avoid areas of beach strand vegetation.

The two COMSATCOMs require a footprint of approximately 0.14 hectare (0.34 acre) each within a fenced area to accommodate the COMSATCOM and equipment. The COMSATCOMs would be placed on existing previously disturbed paved areas to further minimize impacts to vegetation. They would also be located within the IDT fenced area. A communication cable to the IDT would be installed along an existing road. Minimal requirements include a concrete base for the COMSATCOMs, an all-weather road to the site, and a prepared surface around the site at least 4.6 meters (15 feet) wide.

Threatened and Endangered Plant Species. No federally proposed or listed candidate, threatened, or endangered plants are located on Midway Atoll.
**Wildlife**

Construction activities would occur on previously disturbed ground and would not significantly impact wildlife. Primary power would be from a commercial source with backup power provided by generator. Noise from the generator may temporarily startle adjacent wildlife, but no long-term impacts are anticipated. Any lighting associated with the Proposed Action would be properly shielded following USFWS guidelines to minimize disorientation impacts to birds.

**Threatened and Endangered Wildlife Species.** No impacts are anticipated to the short-tailed albatross, Hawaiian monk seal, or basking sea turtles, which would all be located along the beach or nearshore water. Personnel would be instructed to stay at least 46 meters (150 feet) away from monk seals on the beach in accordance with current rules.

**Environmentally Sensitive Habitat**

The small wetland on the island, critical habitat for the Hawaiian monk seal, which is not located on Sand Island, and established Marine Protected Areas would not be affected by site preparation activities.

**Operation**

**Vegetation**

No impacts to vegetation would result from operation of the IDT and COMSATCOMs.

**Wildlife**

During normal operations, the IDT would not transmit except for a few minutes during annual testing of the equipment. Given the short duration of transmission, no adverse impacts to biological resources are anticipated. Most operational impacts to wildlife from the IDT and COMSATCOMs would come from security lighting and noise from backup electrical generators required for the site. The lighting and noise could encourage species less tolerant of these disturbances to avoid the area. Any lighting associated with the Proposed Action would be properly shielded following USFWS guidelines to minimize disorientation impacts to birds. Generator noise could range from 80 to 85 dBA at up to 105 meters (344 feet). These noise levels would only occur a couple of hours a week during maintenance activities required for backup generators, with minimal impact to wildlife adjacent to the site.

**Threatened and Endangered Wildlife Species.** No impacts are anticipated to the short-tailed albatross, Hawaiian monk seal, or basking sea turtles, which are all located along the beach or nearshore water outside of the highest noise levels. Personnel would be instructed to stay at least 46 meters (150 feet) away from monk seals on the beach in accordance with current rules.

**Environmentally Sensitive Habitat**

The small wetland on the island, critical habitat for the Hawaiian monk seal (which is not located on Sand Island), and established Marine Protected Areas would not be affected by site preparation activities.
4.2.2.3 Sensors
Mobile telemetry would be set up on an existing gravel pad or paved area. Operation of a 10 kW generator would cause noise levels of 80 to 85 dBA at up to 344 feet (105 meters). These noise levels would occur 24 hours per day for up to 3 weeks, five times per year, in support of missile flight tests, with minimal impact to wildlife.

4.2.2.4 Cumulative Impacts
The limited operation of the IDT and COMSATCOMs when combined with current activities on Midway is not expected to result in cumulative impacts to vegetation or wildlife.

4.2.2.5 Mitigation Measures
No biological resources mitigation measures are proposed for the GMD ETR activities at Midway.

4.2.3 HAZARDOUS MATERIALS AND HAZARDOUS WASTE—MIDWAY
A general description of impact on hazardous material and waste management is provided in the beginning of section 4.1.6. Pollution prevention, recycling, waste minimization, IRPs, USTs, ASTs, asbestos, lead-based paint, and PCBs have been considered. Potential impacts from GMD ETR activities are addressed as applicable.

4.2.3.1 No Action Alternative
Under the No Action Alternative, IDT and COMSATCOM facilities would not be constructed for the GMD ETR and Midway would continue to serve as a National Wildlife Refuge under direction of the USFWS. There would be no impact to hazardous materials and waste management practices at Midway.

4.2.3.2 Alternatives 1, 2, and 3
4.2.3.2.1 In-Flight Interceptor Communication System Data Terminal
Installation and operation of an IDT and COMSATCOMs, in and of itself, would have minimal impact on the atoll with respect to hazardous materials use or hazardous waste generation. In accordance with DoD requirements, hazardous materials management would be planned into the installation and operation activities from conceptual design forward.

Construction
IDT and COMSATCOM construction would essentially be the same as routine commercial construction of a small communications facility and would result in only minor disturbance of the immediate area. Equipment would be fabricated prior to delivery, and only final assembly would be required on site. “Environmentally preferable” materials would be used where possible. Potentially hazardous materials such as adhesives, paints and low-toxicity cleaning products would be used to install and maintain the equipment, and diesel fuel would be used for electrical generator operation. Only the minimum quantity of material necessary to perform the work would be transported to the atoll. Pollution Prevention, Recycling, and Waste Minimization
would be practiced in accordance with applicable EPA, State of Hawaii, DoD, U.S. Army, and USFWS requirements. IRP sites from the Navy CLEAN program would not be affected.

Temporary storage tanks and other facilities for the storage of hazardous materials would be located in protected and controlled areas designed to comply with site-specific spill prevention and countermeasure plans. Hazardous wastes generated during construction would consist of materials such as waste oils, hydraulic fluids, cleaning fluids, cutting fluids, and waste antifreeze. The minimal quantities of hazardous waste that could potentially be generated would be containerized and returned to Hawaii and/or the continental United States by the individual contractors for disposal.

Any spill of a hazardous material or hazardous waste that may occur during construction would be quickly remediated in accordance with the contractor's Stormwater Pollution Prevention Plan and Project SPCC Plan that would be developed. All hazardous materials used and hazardous waste generated during construction would be handled in accordance with applicable federal, state, and local regulations.

**Operation**

IDT operation would utilize electrical power for sending and receiving signals. Electrical power could be from the local electrical grid or from a dedicated standby diesel generator. Diesel fuel for the generator would be stored in ASTs. The ASTs would be double walled and have secondary containment to conform to API standards. No USTs would be used.

Although not normally considered hazardous waste (designation varies by state), used POL would be generated in small amounts. Tank bottoms from the ASTs would be withdrawn periodically and the fuel disposed of as used (nonhazardous) POL. Generator engine oil changes would likewise result in generation of small amounts of used motor oil. Also, small amounts of potentially hazardous waste would be generated by maintenance and housekeeping activities at the site. Handling of disposal of the minimal quantities of hazardous waste generated from IDT operation would the same as discussed under IDT construction.

**4.2.3.2.2 Sensors**

Mobile telemetry operation impacts would be similar to that described above for the IDT. A 10-kW generator would provide power to the mobile telemetry. Handling of POL waste would be as described for the IDT.

**4.2.3.3 Cumulative Impacts**

The limited operation of the IDT and COMSATCOM when combined with current and planned activities at Midway is not expected to result in cumulative hazardous materials and hazardous waste impacts.

**4.2.3.4 Mitigation Measures**

No hazardous waste management/hazardous materials mitigation measures are proposed for the GMD ETR activities at Midway.
4.3 REAGAN TEST SITE

Potential impacts of construction, building modification, and missile launches on air quality, biological resources, hazardous materials and waste, and health and safety have been addressed in detail in the applicable NEPA documents listed in appendix A, such as the USAKA Supplemental EIS and the USAKA Temporary ETR EA. Based on the prior analyses in those documents, and the effects of past target and interceptor launch activities, the potential environmental impacts from the proposed GMD activities are expected to be minimal, as discussed in the following sections.

4.3.1 AIR QUALITY—REAGAN TEST SITE

4.3.1.1 No Action Alternative

As described in section 2.2.1, missile flight test activities would continue at RTS. As determined in the Theater Missile Defense ETR EIS (U.S. Army Space and Strategic Defense Command, 1994) and the Supplemental USAKA EIS (U.S. Army Space and Strategic Defense Command, 1993a), emissions from a typical launch at RTS (i.e., one strategic launch vehicle) are assumed to be 7.14 metric tons (7.88 tons) of carbon monoxide, 5.18 metric tons (5.71 tons) of hydrogen chloride, and 9.27 metric tons (10.22 tons) of aluminum oxide. In the USAKA Supplemental EIS, air emission modeling was performed to predict maximum short-term concentration of the previously mentioned exhausts. The exhaust emission presented in the USAKA Supplemental EIS is shown in table 4.3.1-1. The worst-case scenario depicted the simultaneous launch of six strategic launch vehicles. Even with such large amounts of exhausts being emitted, the modeling results predicted that no UES or guidance levels would be exceeded.

4.3.1.2 Alternative 1

4.3.1.2.1 Ground-Based Interceptors

Construction

Alternative 1 would only require minor interior modifications to existing facilities on Meck; therefore, there would be no air quality impacts to the regional air quality due to construction.
Operation

Pre-Launch Activities
Operation activities for single and dual GBI launches at RTS up to five times a year would be similar to those described in section 4.1.1.2.1 for KLC. An accidental release of liquid fuel and liquid oxidizer from the EKV would be similar to that described for KLC (table 4.1.1-5). The implementation of approved emergency response plans would limit the impact of such a release. While not defined in detail, pre-launch activities would be expected to result in very low, insignificant emissions.

Offsite power sources with backup emergency generators would continue to be used for the existing facilities at RTS. Emissions at RTS are covered under an existing Document of Environmental Protection.

Launch Activities
Launch activities for a single or dual launch would be similar to previous launches at RTS. Possible emissions that would result from a GBI launch are listed in table 4.1.1-8. As described in section 3.3.1, air quality at RTS is considered good. It is expected that background levels would not add significantly to the ambient air concentrations.

Potential GBI exhaust emissions are 0.2 to 0.3 times the level of the launches modeled in the No Action Alternative, as shown in table 4.3.1-2. It is anticipated that the air quality impacts due to the dual launch of GBIs would be less than those modeled for six simultaneous strategic missile launches in the Supplemental USAKA EIS. The proposed GBI missile would not be expected to cause a significant impact to regional air quality surrounding RTS.

Post-Launch Activities
Activities performed during post-GBI launch would include the removal of all mobile equipment and assets brought to RTS. The removal could result in small localized amounts of fugitive dust, which would have a minor impact to air quality. However, this impact would be minimized further through the use of dust suppression methods previously discussed.
4.3.1.2.2 Targets

Construction

With the implementation of Alternative 1, similar minor modifications to existing facilities at RTS for GBI launches would occur for target launches. An older silo would be modified to accommodate some target missiles. A new launch pad on Meck would be required to support dual target launches. A new launch pad would disturb approximately 0.4 hectare (1.0 acre) during construction. Table 4.3.1-3 shows potential construction emissions.

</tbody>
</table>

PM-10 produced during construction would be reduced by half through the use of dust suppression measures such as periodically watering areas being graded and wet sweeping or otherwise removing soils and mud deposits from paved roadways and parking areas. Proper tuning and preventive maintenance of construction vehicles would serve to minimize exhaust emissions.

Operation

Pre-Launch Activities

Pre-launch activities at RTS include the transportation and assembly of the target. The mobile exhaust emissions resulting from transportation would be intermittent and would not have a measurable impact to regional air quality.

Launch Activities

Proposed target launches would be similar to previous rocket launches at RTS. These land launched target missiles could consist of one of several types of missiles including Strategic Target System, Minuteman II Target, Peacekeeper Target, and Trident I (C4) Target. Table 4.1.1-13 lists missile propellant information and table 4.1.1-14 lists emission constituents for each proposed missile. Up to five launches per year would occur at RTS over the duration of the program.

Potential target exhaust emissions from a dual target launch are anticipated to be, at most, 60 percent of the level of the launches modeled in the No Action Alternative, as shown in table 4.3.1-4. It is expected that the air quality impacts due to the dual launch of any of the targets...
listed in table 4.3.1-4 would be less than those modeled for six simultaneous strategic missile launches in the Supplemental USAKA EIS. The proposed target missile would not be expected to cause a significant impact to regional air quality surrounding RTS.

</tr>
</tbody>
</table>

Post-Launch Activities
Activities performed during post-target flight would include the removal of all mobile equipment and assets brought to RTS. The removal could result in small, localized amounts of fugitive dust, which would have a minor impact to air quality. However, this impact would be minimized further through the use of dust suppression methods previously discussed.

4.3.1.2.3 Sensors
All sensors to be utilized in Alternative 1 previously exist at RTS and are currently in use. Minor software and interior modifications could be performed to these elements; therefore, there would be no construction air quality impacts at RTS for sensors. Operation of existing range radar at RTS would be covered under the existing Document of Environmental Protection.

4.3.1.2.4 SBX
Construction
Warehouse and administrative space construction would occur in previously disturbed areas. All construction activities would be conducted in accordance with appropriate regulations and permits. Other than minor, short-term impacts from construction, no adverse effects to regional air quality are expected.

Operation
Operational emissions aboard the SBX would be limited to the exhaust produced by generators and maintenance. Maintenance-related emissions would consist primarily of minimal levels of volatile organic compound emissions and are not expected to have a significant impact on air quality.

65 Percent and Fully Populated SBX
Based on five tests per year, the SBX would be at the RTS PSB for 7 months. For conservative analysis purposes, 9 months will be used. The SBX is being analyzed as a mobile source with
an expected use of 6,600 hours per year (24 hours a day for 9 months) at a single location, approximately 5 to 6 kilometers (3 to 4 miles) north of the Kwajalein harbor. The SBX on-board power plant planned for use would include eight 3.64-MW diesel driven generators. While at the PSB, only three of the generators would be used. One would operate continually while in port for daily ship functions. The other two generators would be required for powering of the 65 percent or fully populated radar for 3 hours per day. The SBX would not be considered a stationary source at RTS; therefore, the standards and procedures for new stationary sources would not be applicable.

Total time includes 6,600 hours of operation of one 3.64-MW generator and 1,650 hours (825 hours each) of operation for the other two generators that would be in operation at the PSB. Total power output for the three 3.64-MW generators would be 30,030 MW hours for the time the SBX is at the PSB. The remaining 3 months of the year it is expected the SBX would be in transit or at one of the SBX operating areas.

4.3.1.3 Alternatives 2 and 3

4.3.1.3.1 Ground-Based Interceptors
Construction and operation of GBI facilities at RTS for Alternatives 2 and 3 would be the same as those described in section 4.3.1.2.1 for Alternative 1.

4.3.1.3.2 Targets
Construction and operation of target launches and associated target facilities at RTS for Alternatives 2 and 3 would be the same as those described in section 4.3.1.2.2 for Alternative 1.

4.3.1.3.3 Sensors
Construction and operation of range sensors at RTS for Alternatives 2 and 3 would be same as those described in section 4.3.1.2.3 for Alternative 1.

4.3.1.3.4 SBX
Construction and operation of the SBX at RTS for Alternatives 2 and 3 would be the same as those described in section 4.3.1.2.4 for Alternative 1.

4.3.1.4 Cumulative Impact
Due to the limited industrialization of USAKA and the surrounding environment, the potential cumulative impacts to air quality due to the proposed interceptor and target facility construction and launches would not be substantial. Missile launches are short-term, discrete events, thus allowing time between launches for emissions products to be dispersed. The 1993 Supplemental USAKA EIS determined that there would be no significant cumulative impacts to air quality under the high level of activity alternative as a direct result of up to 14 launches of six missiles simultaneously per year. The modeling resulted in no predicted annual impacts that exceed UES Ambient Air Quality Standards. It is not likely that the Proposed Action in conjunction with current planned or anticipated launches would exceed this level of activity. The
anticipated number of missile launches from RTS in support of the GMD ETR would be up to five missiles (GBI and targets combined) per year.

4.3.1.5 Mitigation
No air quality mitigation measures are proposed for GMD ETR activities.

4.3.2 AIRSPACE—REAGAN TEST SITE

4.3.2.1 No Action Alternative
Under the No Action Alternative, the GMD ETR would not be established, and interceptor and target launch scenarios would not require the SBX for testing under operationally realistic conditions. As described in section 2.2.1, operations currently conducted at RTS would continue.

4.3.2.2 Alternatives 1, 2, and 3
The Proposed Action for all alternatives related to airspace would be full power emissions from the SBX while at the mooring location north of Kwajalein.

4.3.2.2.1 SBX Operation

Controlled and Uncontrolled Airspace
Unrestricted operation of the SBX at the mooring location would have the potential to adversely affect aircraft operations. Both the DoD and the FAA have standards for EMR interference to aircraft, which should not be exceeded. DoD uses MIL-STD-464 standards; therefore, military aircraft must be hardened or protected from EMR with a peak power threshold up to 3500 volts per meter (V/m) and 1270 V/m (average power). The SBX would not exceed these levels. Commercial aircraft must be hardened or protected from EMR levels up to 3000 V/m (peak power) and 300 V/m (average power) as mandated by the Federal Aviation Association (FAA) by Notice 8110.71, Guidelines for the Certification of Aircraft Flying through High Intensity Radiated Field Environments. The SBX would not exceed the 3000 V/m peak power threshold. The SBX could exceed the 300 V/m average power threshold. The average power threshold is based upon reducing the time of exposure of aircraft avionics (electronic equipment) to High Intensity Radiated Fields in order to preclude shortening the life of the aircraft avionics. Therefore, the concern here is not interference but is a reduction in life of the aircraft avionics/electronic equipment. As shown in table 2.1.4-2, the fully populated radar has a potential for interference with aircraft (exceeding the 300 V/m average power threshold) out to a distance of 19 kilometers (11.8 miles) from the SBX.

In order to avoid or minimize adverse effects from EMR/EMI, DoD has established a coordination process with responsible agencies and airspace users. A full EMR/EMI survey and analysis would be conducted by the Joint Spectrum Center, in coordination with the FAA, USAKA, and other potentially affected users. The survey is used in preparing a DD Form 1494 that would be required as part of the spectrum certification and frequency allocation process. The completed
DD Form 1494 that has been processed and approved by the appropriate national and international authorities would be required prior to SBX testing.

The results of the survey would also be used to define the operating area for the SBX (acceptable azimuths and operating angles). The maximum operating area would be all azimuths (360 degrees), and all angles up to 90 degrees. The maximum potential interference distances are listed in table 2.1.4-2 and on figure 3.3.2-1.

The actual SBX operating area at the mooring location would be restricted in order to minimize impacts to aircraft operations, EEDs, and communication equipment. The boundaries of the SBX high energy radiation area would be configured to minimize impacts to aircraft operations and other potentially affected systems. The establishment of this SBX high energy radiation area would not impose any new flight restriction requirements. The operating area would be similar to the existing operating area for the GBR-P radar at Kwajalein (figure 4.3.2-1). As shown in the figure, the GBR-P is restricted from radiating in several areas. These include the arrival and departure corridors for Bucholz Army Airfield, in the direction of the rest of Kwajalein Island, and in the direction of other nearby islands.

SBX operations would be coordinated with the FAA and Kwajalein and would be scheduled to occur during hours of minimal aircraft operations. Consequently, there would be no reduction in the amount of navigable airspace, and thus no impacts to the controlled and uncontrolled airspace in the ROI would result.

Special Use Airspace
There is no special use airspace within the ROI. Consequently, there would be no impacts to special use airspace.

En Route Airways and Jet Routes
Two en route high altitude airways (R 584 and A 222) enter the 65 percent and fully populated aircraft interference areas and terminate at Kwajalein. There are additional approach and departure routes within the ROI that would also need to be considered when defining the SBX operating area. The SBX would be programmed to limit RF emissions in the direction of airways that pass within the potential interference distance. In addition, since the radar beam is in constant motion, it is highly unlikely that the SBX would illuminate an aircraft long enough to affect the on-board electronics.

Airports and Airfields
Bucholz Army Airfield is located on Kwajalein, approximately 5 to 6 kilometers (3 to 4 miles) south of the proposed mooring location. With the controls placed on the SBX in a manner similar to the GBR-P radar, standard instrument approach and departure procedures at the airfield would continue unhindered. Existing airfield or airport arrival and departure traffic flows would also not be affected and access to the airfield would not be curtailed. All arriving and departing aircraft and all participating military aircraft are under the control of the Bucholz Army Airfield Control Tower; thus, there would be no airfield conflicts in the ROI under the Proposed Action, and no impact.
Notional GBR-P Operating Area

Figure 4.3.2-1
Emissions from the XBR may also potentially degrade the overall system performance of in-band airborne and ship-based systems such as fire control, bomb/navigation in military aircraft, and weather radars in both civilian and military aircraft, which all operate in the X-band (8 to 12 GHz). However, the SBX high-energy radiation area would be configured to avoid impacts to these airborne and ship-based systems.

4.3.2.3 Cumulative Impacts

Because the SBX operates in different frequency ranges than most aircraft radars, there would be limited potential for an incremental, additive cumulative electromagnetic effect upon the operation of an air navigation facility or the signal used by aircraft. The use of the required scheduling and coordination process, and adherence to applicable DoD directives and U.S. Army regulations concerning radar operations would preclude the potential for significant incremental, additive, cumulative impacts.

No other projects in the airspace ROI have been identified that would have the potential for other incremental, additive cumulative impacts to controlled or uncontrolled airspace, special use airspace, en route airways and jet routes, or airfields and airports in the ROI.

4.3.2.4 Mitigation Measures

The SBX high energy radiation area would be configured to mitigate potential impacts to aircraft and other potentially affected systems, and would be published on aeronautical charts. In addition to charting the SBX high energy radiation area notice, information would be published in the Airport Facility section of the FAA Airport Guide, and local NOTAMs would be issued. Additionally, flight service personnel would brief pilots flying in the vicinity about the SBX high energy radiation area.

4.3.3 BIOLOGICAL RESOURCES—REAGAN TEST SITE

Regulations governing endangered species and wildlife resources at RTS are specified in UES Section 3-4. Water quality and reef protection standards at RTS are in UES Section 3-2 (U.S. Army Space and Missile Defense Command 2001)

4.3.3.1 No-Action Alternative

If the GMD ETR is not established, the following activities would still continue at RTS: launch of GBIs, use of extensive range instrumentation, use of the GBR-P ground-based XBR, use of existing IDT facilities, and missile intercepts in the BOAs north and northeast of RTS. Impacts to biological resources would be minimal as described in the applicable NEPA documents listed in appendix A, such as the USAKA Supplemental EIS and the USAKA Temporary ETR EA.
4.3.3.2 Alternative 1

4.3.3.2.1 Ground-Based Interceptors

Alternative 1 would require the use of existing GBI silos on Meck, a Missile Assembly Building, missile storage facility, maintenance and storage facility, and launch control facility to support GBI launches for the GMD ETR.

GMD ETR program personnel would remove all mobile equipment/assets brought to the installation at the conclusion of its testing activities. Transportation for removal of equipment would be the same as when it was brought into the installation. These activities would result in impacts similar to, but less than, those caused by site preparation. Specific restoration actions, if necessary, would be determined on a case-by-case basis.

Construction

Only minor maintenance activities would be required.

Vegetation

No new construction or other ground-disturbing activities are planned; therefore, there would be no impacts to vegetation.

Wildlife

Personnel would be instructed to avoid areas designated as avian nesting or roosting habitat and to avoid all contact with any nest that may be encountered. Sea turtles or turtle nests would also be avoided. No site preparation activities are planned that could impact Essential Fish Habitat.

Environmentally Sensitive Habitat

No site preparation activities are planned that could impact reef slopes and flats or seagrass beds.

Operation

Dual target launches could potentially occur. Dual launches could result in a slightly larger affected area and longer duration of disturbance to wildlife. Impacts would in some cases be slightly greater than, but similar to, those analyzed below for single launches.

Vegetation

Meck has been extensively altered by human activity, and little native vegetation remains to serve as wildlife habitat. No additional impacts to vegetation are expected from continued GBI launches.

Wildlife

Results of monitoring conducted for a Strategic Target System launch from KTF at PMRF indicated little effect upon wildlife due to the low-level, short-term hydrogen chloride emissions (U.S. Army Space and Strategic Defense Command, 1993b). The program included marine
surveys of representative birds and mammals for both pre-launch and post-launch conditions. Studies on representative birds and mammals reviewed in the *Final EIS for the Strategic Target System* (U.S. Army Strategic Defense Command, 1992) also indicated that low-level, short-term exposure to hydrogen chloride would not adversely affect threatened or endangered species or other wildlife. Aluminum oxide and hydrogen chloride do not bioaccumulate; therefore, no indirect effects to the food chain are anticipated.

An early flight termination or mishap could result in debris impacts along the flight corridor, which may temporarily impact fishing activities in the immediate area. Due to the small amount of propellant involved and the limited number of launches, the project is not anticipated to adversely affect trust marine resources. The potential ingestion of toxins by fish species, which may be used for food sources, would be remote because of the diluting effect of the ocean water and the relatively small area that would be affected. The primary flight test activity that may have an effect on wildlife within the flight test corridor is the actual intercept of the target missile. Debris impact areas for both the interceptor and target vehicles would be located over the Mid-atoll Corridor of the Kwajalein Lagoon or the BOA.

Any debris from mishaps landing in the Kwajalein Lagoon in approximately 50 meters (164 feet) of water would be recovered. The debris is not expected to contain hazardous materials. Unburned solid fuel is hard and rubber-like, and any ammonium perchlorate would dissolve slowly out of the rubber-like binder, producing ammonia and chlorine that would disperse into the marine waters. A recent study conducted for the U.S. Air Force (Lang, et al., 2001) measured the amount of perchlorate lost from solid propellant samples immersed in fresh and salt water. From the measurement of the concentration of the perchlorate ion in solution, the mass fraction loss of the propellant sample due to perchlorate leaching was calculated. The results are presented in the KLC Water Resources section, table 4.1.14-2. As shown in the table, it would take approximately 270 days for 90 percent of the perchlorate to leach out of solid propellant that lands in the ocean (at 29°C [84°F]). The perchlorate would be expected to be diluted as it mixes with the surrounding water. Larger pieces of propellant would be recovered following a mishap in the lagoon, further minimizing the potential for perchlorate contamination.

Disturbance to wildlife from the launches would be brief and is not expected to have a lasting impact nor a measurable negative effect on migratory bird populations. Wildlife such as waterfowl would quickly resume feeding and other normal behavior patterns after a launch is completed. Waterfowl driven from preferred feeding areas by aircraft or explosions usually return soon after the disturbance stops, as long as the disturbance is not severe or repeated (Federal Aviation Administration, 1996).

**Threatened and Endangered Wildlife Species.** An early flight termination or mishap could result in debris impact along the flight corridor. Sensitive marine species are widely scattered, and the probability of debris striking a threatened or endangered species is considered remote. For example, according to the *Strategic Target System EIS*, which assessed the low potential in regard to debris striking whale species, the probability of an impact is less than a 4.6 chance in 1 million (4.6 x 10⁻⁶) (U.S. Army Strategic Defense Command, 1992).

Thus, debris impact and booster drops in the BOA are not expected to adversely affect marine mammal species protected by the UES. In addition, the probability is rather low that migratory whales or sea turtles would be within the area to be impacted by falling debris and boosters.
**Environmentally Sensitive Habitat**

Proposed nominal launch activities would not impact sensitive habitat such as coral reefs.

### 4.3.3.2.2 Targets

Alternative 1 would require the use of existing facilities on Meck, including a Missile Assembly Building, missile storage facility, maintenance and storage facility, and launch control facility for target launches in support of the GMD ETR. Dual launches of target missiles would occur from a modified Payload Launch Vehicle GBI silo on Meck and a new launch pad on Meck.

### Construction

Other than the construction of a new launch pad on Meck, only minor maintenance activities and internal modifications to an existing silo would be required.

### Vegetation

Meck has been extensively altered by human activity, and little native vegetation remains to serve as wildlife habitat. The new target launch pad on Meck would require installation of a launch stool on reinforced concrete within a previously disturbed area. No impacts to vegetation are expected.

### Wildlife

Disturbance to wildlife from the construction noise and temporary increase in personnel would be brief and is not expected to have a lasting impact nor a measurable negative effect on migratory bird populations. Personnel would be instructed to avoid areas designated as avian nesting or roosting habitat and to avoid all contact with any nest that may be encountered. Sea turtles or turtle nests would also be avoided. No site preparation activities are planned that could impact Essential Fish Habitat.

**Environmentally Sensitive Habitat**

No site preparation activities are planned that could impact reef slopes and flats or seagrass beds.

### Operation

Dual target launches could potentially occur. Dual launches could result in a slightly larger affected area and longer duration of disturbance to wildlife. Impacts would in some cases be slightly greater than, but similar to, those analyzed below for single launches.

### Vegetation

No impacts to vegetation would occur as a result of launch activities on Meck, since the new target launch site would be located within a previously disturbed area.

### Wildlife

Impacts to wildlife from target missile launches would be similar to those discussed above for GBI launches.
Environmentally Sensitive Habitat
Impacts to sensitive habitat would be the same as those discussed above for GBI launches.

4.3.3.2.3 Sensors

Existing range sensors at RTS would be used, including the Advanced Research Project Agency Lincoln C-Band Observable Radar and Long-range Tracking and Instrumentation. Both of these tracking radars are located on Roi-Namur at RTS. Additional radars include the TPS-X, Millimeter Wave Radar, Tracking and Experiment Discrimination Experiment Radar, and two MPS-36 C-band general-purpose instrumentation radars located at RTS. Although the potential for mainbeam exposure thermal effects from these radars to birds exists; mitigating these concerns is the fact that radar beams are relatively narrow and constantly in motion. To remain in the beam for any period requires that a bird fly directly along the beam axis, or that a hovering bird does so for a significant time. Thus, although the potential for adverse effects exists, the probability of such an occurrence happening frequently is considered low. The potential for impacts from the use of these radars have been analyzed in prior environmental documentation and determined to be not significant.

Personnel would be instructed to avoid areas designated as avian nesting or roosting habitat and to avoid all contact with any nest that may be encountered. Sea turtles or turtle nests would also be avoided. No site preparation activities are planned that could impact Essential Fish Habitat.

4.3.3.3 SBX

Construction

Although the piers at the Kwajalein harbor do not offer adequate depth to accommodate the draft of the SBX, the vessel can enter the Kwajalein lagoon and moor in a protected anchorage. RTS has a full complement of supply and fueling vessels. The mooring site would be approximately 5 to 6 kilometers (3 to 4 miles) north of the Kwajalein harbor. The SBX would enter the lagoon either through South Pass on the west side of the atoll or at Mellu Pass on the north side. Both passes offer sufficient depth to accommodate the vessel; however, Mellu Pass offers a much greater width for maneuverability. Personnel would be ferried to the SBX each day either by watercraft or helicopter.

Existing facilities with 900- to 1,500-square-meters (3,000- to 5,000-square-feet) of environmentally controlled warehouse would potentially be required for SBX operations. Any facility modification required to provide support to the SBX would occur in previously disturbed areas in accordance with host installation guidelines and regulations.

Typical noise levels at 15 meters (50 feet) from construction equipment range from 70 to 98 dBA. The effects of noise on wildlife vary from serious to no effect in different species and situations. Behavioral responses to noise also vary from startling to retreat from favorable habitat, due partly to the fact that wildlife can be very sensitive to sounds in some situations and very insensitive to the same sounds in other situations (Larkin, 1996). Most wildlife is known to exhibit a startle response when exposed to short-term noise impacts. The combination of increased noise levels and human activity would likely displace some small mammals and birds that forage, feed, nest, or have dens within this 15-meter (50-foot) radius. However, sufficient
foraging and feeding habitat occurs in adjacent areas. Studies (U.S. Department of the Air Force, 1997b) indicate that birds usually show signs of disturbance, such as fluttering of wings, when a noise event occurs, but quickly return to normal behavior after the event. Although construction activities could cause flushing (birds suddenly flying up), this is a common reaction to sudden natural sounds that only slightly increases the energy expenditure of individual birds. Construction is therefore not expected to have a long-term significant adverse effect on wildlife. Other than these minor, short-term impacts from noise, such as startling and temporary displacement, no adverse effects to biological resources are anticipated.

Operation

The SBX is a high-powered radar system that would use a pulsed microwave beam to perform tracking, discrimination, and kill assessments of incoming ballistic missile warheads. Since this system has the potential for exposing regions in its vicinity to EMR, consideration has been given to the evaluation of the potential for any adverse impacts that EMR may have on biological resources.

As described in section 2.1.4, the SBX would be mounted on a semi-submersible platform. The platform would be self-propelled in open water with a cruising speed of approximately 15 kilometers per hour (8 knots), but assisted by tug(s) while in port. Total height of the SBX above the water line including the XBR radome would be approximately 76.3 meters (250 feet) at transit draft. The main beam would not be directed toward the ground or water surface, would have a lower limit of 10 degrees above horizontal for calibration and maintenance testing while at the PSB, and thus would not directly illuminate the surface. The transmit/receive RF emission pattern would be mostly contained within a narrow main beam. Table 2.1.4-2 lists the EMR potential interference distances. The total amount of RF radiation per week would be approximately 5 to 6 hours. A full EMR/EMI survey and analysis would be conducted by the Joint Spectrum Center, in coordination with the FAA, DOT, and other potentially affected users. An operating permit would be negotiated based on the results of the EMR/EMI survey.

In terms of the potential for EMR impacts on wildlife, the GBR Family of Radars EA (U.S. Army Program Executive Office Missile Defense, 1993) analyzed potential impacts on wildlife from EMR. This EA determined that several factors significantly reduce the potential EMR exposure for birds and other wildlife. The radar main beam would normally be located at least 2 degrees above horizontal, which limits the probability of energy absorption by surface-oriented wildlife. The radar beam would normally be in motion, making it extremely unlikely that a bird would remain within the most intense area of the beam for any considerable length of time. The size of the beam is relatively small, which further reduces the probability of bird species remaining within this limited region of space, even if the beam were still. (Ballistic Missile Defense Organization, 2000)

The analysis methods used to evaluate potential effects of RF radiation on birds is the MPEL, which defines the maximum time-averaged radio frequency power density allowed for uncontrolled human exposure (and by extrapolation, to birds and other species). The MPEL method is independent of body size or tissue density being exposed. Analysis conducted during preparation of the GBR Family of Radars EA (U.S. Army Program Executive Office Missile Defense, 1993) was based on a conservative approach of limiting the microwave energy absorption rate on the Aplomado falcon (*Falco femoralis*), a bird listed as endangered by the USFWS and the State of New Mexico. The energy absorption rate was based on the falcon remaining continuously within the main beam of the GBR. The absorption rate was then
compared to the bird’s resting metabolic rate. The analysis indicated power densities would have to exceed 42 mW/cm² to affect the falcon. Power densities of 38 to 61 mW/cm² have been determined necessary to affect other birds weighing up to 3.5 kilograms (7.7 pounds). Analysis conducted during preparation of the prototype High Power Discrimination Radar at PMRF was based on the potential effects on the Laysan albatross (U.S. Department of the Navy, 2002a).

The analyses were based on the conservative assumption that the energy absorption rate of a bird’s body was equal to its resting metabolic rate and that this may pose a potential for an adverse effect. Birds in general typically expend energy at up to 20 times their resting metabolic rates during flight. Since birds are not likely to remain continuously within the radar beam and the power density is not expected to exceed levels stated above that could impact birds, the likelihood of harmful exposure is not great. (Ballistic Missile Defense Organization, 2000)

Potential impacts from EMR from the XBR on wildlife have been compared to the existing Cobra Dane radar operating on Eareckson Air Station on Shemya Island, Alaska. The Cobra Dane operates in the L-band (1,000 to 2,000 MHz), while the proposed SBX would operate in the X-band (8,000 to 12,000 MHz). The X-band has less potential to cause thermal heating in biological resources than the L-band. Like the Cobra Dane, the proposed SBX main beam would be constantly moving and would not be stationary over one area. The USFWS has not noticed die-offs of birds below the Cobra Dane radar (Martin, 1999). Overall, it is expected that no bird deaths would be expected as a result of operation of the SBX. (Ballistic Missile Defense Organization, 2000)

The total height of the SBX above the water line including the XBR radome would be approximately 76.3 meters (250 feet) at transit draft and the SBX radar main beam would not be directed toward the ocean’s surface. Since marine mammals would normally be found below the surface of the water, this signal height would be safely above any surfacing mammals. RF radiation does not penetrate the surface of water to any great degree. The power density level just below the surface of the ocean would not exceed the permissible human exposure level for uncontrolled environments. (U.S. Department of the Navy, 2002a) No adverse impacts would occur to whales, other marine mammals, or sea turtles at least 1.3 centimeters (0.5 inch) below the surface. It is also highly unlikely that an individual would be on or substantially above the surface of the water for a significant amount of time during the 3 to 6 hours per week that the SBX radar would be operating. For these reasons, no effects are anticipated on humpback whales, other marine mammals, or sea turtles that might be present in the vicinity of the homeport and transit locations. Operation of the SBX would not require delays if whales and other marine mammals are observed. Therefore, no further action regarding whales or sea turtles is required pursuant to the Endangered Species Act and the Marine Mammal Protection Act.

The SBX vessel would incorporate marine pollution control devices such as keeping decks clear of debris, cleaning spills and residues, and engaging in spill and pollution prevention practices in compliance with the Uniform National Discharge Standards (UNDS) provisions of the Clean Water Act. The potential for impacts to marine mammals or sea turtles due to an accidental release of diesel fuel is considered low. The relatively slow speed of the SBX platform would preclude the potential for collision with a free-swimming marine mammal. Overall, no adverse impacts to marine mammals or sea turtles are anticipated.
4.3.3.4 Alternatives 2 and 3

The Proposed Actions and environmental effects at RTS under Alternatives 2 and 3 are identical to those described under Alternative 1.

4.3.3.5 Cumulative Impacts

The limited amount of facility modification planned on RTS would not likely result in cumulative impacts to biological resources. The 1993 Supplemental USAKA EIS determined that there would be no significant cumulative impacts to biological resources under the intermediate level of activity alternative as a direct result of launching up to 28 strategic launch vehicles per year from Meck. The anticipated number of missiles launches from RTS in support of the GMD ETR could be up to five missile launches (GBI and targets combined) per year. No significant cumulative impacts to biological resources have been identified as a result of prior launch-related activities from RTS. The GMD ETR activities when combined with current and proposed launch activities on RTS would not increase the total number of annual launches currently allowed. These activities would have negligible cumulative impacts on biological resources.

4.3.3.6 Mitigation Measures

As a standard practice, personnel would be instructed to avoid areas designated as avian or sea turtle nesting or avian roosting habitat and to avoid all contact with any nest that may be encountered.

4.3.4 HAZARDOUS MATERIALS AND HAZARDOUS WASTE—REAGAN TEST SITE

This section addresses potential impacts that could result from the storage and use of hazardous materials and the generation and disposal of hazardous waste associated with launch operations from the RTS.

A general description of impact on hazardous material and waste management is provided in appendix B. Pollution prevention, recycling, waste minimization, IRPs, USTs, ASTs, asbestos, lead-based paint, and PCBs have been considered. Potential impacts from GMD ETR activities are addressed under each alternative as applicable.

4.3.4.1 No Action Alternative

If the GMD ETR is not established, the following activities would still continue at RTS: launch of GBIs, use of extensive range instrumentation, use of the GBR-P ground-based XBR, use of existing IDT facilities, and missile intercepts in the BOAs north and northeast of RTS. Impacts to hazardous materials and hazardous waste management practices would be minimal as described in the previous NEPA documents listed in appendix A.
4.3.4.2 Alternative 1

4.3.4.2.1 Ground-Based Interceptors

Under Alternative 1, Meck Island would serve as the location for missile assembly and as well as launch. GBI launches would utilize existing GBI facilities on Meck as described in section 2.3.1.3.

Construction

Alternative 1 would only require minor interior modifications to existing facilities on Meck; therefore, only minor impacts to hazardous materials and waste management practices would be expected.

Operation

Pre-Launch Activities

Missile components would likely be brought to Kwajalein Island as the initial arrival point at the USAKA. Kwajalein Island would also serve as the supply point for consumable materials to be employed during interceptor vehicle preflight assembly and checkout operations, and consumable supplies needed for the maintenance of the ongoing radar operations. Some of the materials in these consumable supplies are considered to be hazardous materials (e.g., contact cleaners for sensor systems). These materials would be stored on Kwajalein in appropriate warehouse facilities before issuance for use on other islands. These materials are similar to hazardous materials already in use for other operations (including standard facility maintenance activities) and represent only a small increase in the total amount of materials to be handled. The quantity of these materials that would be used represents a de minimis increase above those already in use and could, therefore, easily be accommodated by the current hazardous materials management systems.

Launch Activities

GBI launch activities would be similar to ongoing activities. The use of hazardous materials during target launch operations would be limited to small amounts of solvent cleaners (e.g., acetone, isopropyl alcohol), ethylene glycol coolant in the radar, and some handling and storage of motor fuels for use in motor vehicle and/or generator systems. Use and management of hazardous materials associated with missile launch activities would continue to be performed in accordance with the requirements of the UES and the RTS Range Safety office.

No USTs exist on Meck Island. ASTs exist for storage of diesel fuel for the power plant and for MOGAS fuel storage.

As discussed in section 3.3.4, hazardous waste management at USAKA is performed in accordance with the UES, which requires shipment of hazardous waste back to the Continental United States for treatment and/or disposal. In most cases, contractors utilize USAKA Prime Contractor Services for waste packaging, manifesting, shipment, and disposal. If contractors make their own hazardous waste arrangements, shipments have to be arranged through USAKA Shipping and Receiving. Minimal hazardous waste generation would occur.
Personnel trained in the appropriate procedures to handle potentially hazardous materials, including spill containment and cleanup, would be on standby should a mishap occur. Such personnel involved in these operations would wear appropriate protective clothing, as necessary.

During normal flight operations there would be no hazardous materials or waste issues associated with flight corridors. If an in-flight malfunction occurs, the range safety officer may initiate flight termination, resulting in missile debris being deposited beneath the flight path. Debris impacts may occur in the Mid-atoll Corridor within the Kwajalein Atoll Lagoon. The potential effects on the ocean environment from hazardous materials associated with missile debris are discussed in section 4.3.2 and have been analyzed in previous NEPA documents, such as the Final EIS for the Strategic Target System (U.S. Army Strategic Defense Command, 1992), with the conclusion that impacts would be minimal.

Post-Launch Activities
Specific restoration actions and debris recovery, if necessary, would be determined on a case-by-case basis in coordination with the procedures of the Facility Services Division of Hazardous Materials.

The types of hazardous wastes that would potentially be generated from GBI launches are similar to wastes already handled at the USAKA. The quantity of hazardous waste that may be generated would represent a small increase over current conditions and would be collected in accordance with the KEEP and UES. Collected wastes would be sent first to point of generation accumulation point on Meck, and on to the USAKA Hazardous Wastes Collection Point (Building 1521) on Kwajalein for eventual shipment to the continental United States and final disposition. The de minimis increase in the quantity of hazardous waste would not significantly impact the existing hazardous waste management and disposal system.

4.3.4.2.2 Targets
Construction
Under Alternative 1, similar minor modifications to existing facilities as described for GBI would occur on Meck. An older silo could be modified to accommodate some target missiles. A new target launch pad on Meck would be required to support dual launches. A new launch pad would consist of basic reinforced concrete and structural steel construction, with little hazardous waste generation.

Many facilities at RTS date from the 1950s through the 1970s. Therefore, any structure, such as an existing launch silo, to be modified for target launch activities would be sampled for asbestos or lead-based paint. Meck Island is essentially PCB-free due to an aggressive PCB removal plan pursued during the 1990s. If asbestos, lead-based paint, or PCBs are encountered during the sampling or modification process, then these materials would be contained and removed in accordance with USAKA SOPs. Such activities are routine at RTS. Launch control wiring and instrumentation modification would also be performed as necessary. Installation of trenches for fiber optic cable and fencing around the launch site would not result in the release of a potentially hazardous material or waste.
Minor construction is normally performed by USAKA Facilities Engineering. Major construction at RTS is routinely contracted and managed by the U.S. Army Corps of Engineers–Pacific Ocean Division, Honolulu District, and performed according to U.S. Army Corps of Engineers requirements, as modified to meet USAKA environmental management requirements. USAKA requirements are incorporated into the U.S. Army Corps of Engineers Statement of Work, and all contractors provide an Environmental Compliance Plan demonstrating knowledge of UES requirements. In accordance with DoD regulation 5200.2R, Personal Security Program Regulation, pollution prevention, waste minimization and recycling would be incorporated into design and construction plans. Construction activities would be performed in accordance with the USAKA Stormwater Pollution Prevention Plan to minimize potential erosion and stormwater runoff.

**Operation**

Pre-launch, launch, and post-launch activities for target missiles would be similar to that described for the GBI.

4.3.4.2.3 SBX

Any facility modification required to provide support to the SBX would occur in previously disturbed areas in accordance with host installation guidelines and regulations. Other than minor, short-term increase from the use of potentially hazardous materials such as paints, solvents and fuels, no adverse effects to ongoing hazardous materials storage and handling are anticipated. The small increases in the amount of potentially hazardous materials used during construction activities would result in generation of added wastes. However, this increase is not expected to be significant and would be accommodated in accordance with existing protocol and regulations.

**Operation**

*Shipboard Hazardous Materials and Waste Management*

The U.S. Navy requires that, to the maximum extent practicable, ships shall retain hazardous waste aboard ship for shore disposal. If hazardous materials are discharged overboard, this must occur more than 370 kilometers (200 nautical miles) from land. Discharging hazardous materials overboard is not standard practice and would only be done as a worst case scenario.

Twenty-five liquid discharges, such as clean ballast, deck runoff and dirty ballast, from the normal operation of Armed Forces vessels are required to be controlled by installation of control technologies or use of management practices (marine pollution control devices) under the UNDS provisions of the Clean Water Act. In compliance with UNDS, the SBX vessel would incorporate marine pollution control devices, such as keeping decks clear of debris, cleaning spills and residues, and engaging in spill and pollution prevention practices, in design or routine operation. All vessels containing ballast water taken on outside the territorial waters of the RMI and intending to discharge ballast water in RMI waters shall off-load ballast water outside of 19 kilometers (12 miles) from shore, and two times the volume of the tank of clean sea water shall be taken on and discharged immediately prior to entry within 19 kilometers (12 miles) of shore. Discharge of ballast from the fuel tanks of watercraft within waters of the RMI shall be minimized and only in accordance with the UES. No vessel shall dispose of sewage (blackwater) or discharge from a marine sanitation device in USAKA controlled waters. (U.S. Army Space and Missile Command 2002).
Increased operations that could take place at RTS would be servicing and maintenance of the SBX. This small increase in servicing operations would not significantly affect hazardous materials management or waste disposal. There would be no significant operational impacts, and no mitigation would be required.

### 4.3.4.3 Alternatives 2 and 3

The Proposed Actions and potential impacts would be the same as those described under Alternative 1. Construction and operation of the SBX at RTS for Alternatives 2 and 3 would be the same as those described in section 4.3.4.2.3 for Alternative 1.

### 4.3.4.4 Cumulative Impacts

Adherence to the hazardous materials and waste management systems on USAKA would preclude the potential accumulation of hazardous materials or waste. The UES establishes emergency response procedures that would aid in the evaluation and cleanup of any hazardous materials released. GMD actions are not expected to result in cumulative hazardous materials and hazardous waste impacts on USAKA. No other projects in the ROI have been identified that would have the potential for incremental, additive cumulative impacts to existing hazardous materials and waste management practices.

### 4.3.4.5 Mitigation Measures

Mitigation measures would be employed in accordance with the UES, which incorporates CEQ NEPA requirements, applicable EPA regulatory requirements, and Executive Order (Presidential) requirements for installations outside the continental United States. In addition other DoD and U.S. Army requirements apply, as tiered requirements under the preceding.

### 4.3.5 HEALTH AND SAFETY—REAGAN TEST SITE

Appendix B includes a description of health and safety issues.

#### 4.3.5.1 No Action Alternative

If the GMD ETR is not established, the following activities would still continue at RTS: launch of GBIs, use of extensive range instrumentation, use of the GBR-P ground-based XBR, use of existing IDT facilities, and missile intercepts in the BOAs north and northeast of RTS. Impacts to health and safety would be minimal as described in the previous NEPA documents listed above and in appendix A.

Planning and execution of GBI launches would be in compliance with federal, state, local, and international health and safety requirements and regulations, as well as RTS standards and procedures. Adherence to such requirements would ensure that potential risks to the general public, workers, and the launch areas do not exceed RCC Standard 321-02 criteria. Therefore, no increase in potential impact to health and safety would be expected as a result of the No Action Alternative.
4.3.5.2 Alternative 1

4.3.5.2.1 Ground Based Interceptor

Construction

Existing RTS missile sites and support facilities on Meck would be used under Alternative 1. Therefore, no potential impact to health and safety from construction activities would be expected.

Pre-Launch

Pre-launch activities, including the transportation, storage and handling of missile components would generally occur as described in sections 3.3.5 and 4.1.7.2.

Missile components would initially be transported to Kwajalein. Kwajalein would also be used as the storage location for all consumable materials (e.g., solvents/cleaners, small parts, tools) that would be used during test flight pre-launch and launch operations. As indicated in section 4.3.4, the primary hazard related to these storage operations would be the potential for explosion/fire of solid fuel motors and/or small explosive actuation devices (used in missile control and the Flight Termination System). At Kwajalein, as at all other USAKA locations, all operations involving explosives (including packaging and handling for movement) would require implementation of a written procedure, which has been approved by the USAKA Safety Office. These operations must be conducted under the supervision of an approved ordnance officer using explosive-certified personnel. All storage and handling of explosives is required to take place in facilities designed to handle explosives and which have been sited in accordance with the requirements of Kwajalein Missile Range Regulation 385-75, Explosive Safety (U.S. Army Kwajalein Atoll, 1993). The regulation specifies the required ESQDs for each facility to ensure safety in the event of explosion, based upon the maximum quantity of explosive material permitted for the facility. This would serve to prevent propagation of explosions to nearby facilities where explosives are also stored.

The explosive devices and materials proposed for use as part of the GBI flight tests would be very similar to those currently stored and used at RTS. Storage operations would not entail any specialized procedures beyond those already in use. Storage facilities (magazines) are available at Kwajalein for proper storage of all explosive materials. Missile assembly buildings, launch silos, launch pads and operations buildings are separated by distances specified in DoD and U.S. Army regulations. The types of facilities, as well as the quantity and type of propellant and other explosives stored in magazines and missile handling areas, are used to determine the distance requirements for structure spacing. In situations such as on Meck where the distance requirements cannot be met by separation, other methods of personnel protection would be implemented. The Meck Control Building and the Systems Technology Testing Facility are hardened and provide protection from fragments.

Launch

Under Alternative 1, launch of GBI missiles would occur at existing RTS facilities on Meck. As lead range, RTS would coordinate with other ranges to track and document safety responsibilities. The principal health and safety concerns would be missile malfunctions on or near the launch silo, potential hazards following a flight termination action and intercept debris impact.
Flight safety studies would be performed to ensure that launches would not compromise range safety requirements and that risk to personnel would be within RCC Standard 321-02 limits. Launches would not be permitted to occur without review and agreement by the Range Safety Officer. Protection circles, based on the payload, missile and launch azimuth, would be established for each launch. Figure 4.3.5-1 indicates the protection circles associated with GMD ETR launch activities. Access to launch sites and the island would be limited to all but mission essential persons. Personnel essential to launch activities would be sheltered in hardened buildings. The GBI flight corridor would be over the islands and BOA. At RTS, thrusted stages that can potentially hazard populated areas must have a flight termination system. (Smith, 2002)

Targets launched from KLC, Vandenberg AFB, air and/or ocean platforms, if not destroyed by intercept, would impact in the BOA. Intercept debris would land in the BOA or possibly on uninhabited islands within the precalculated debris hazard/impact zone. When containment within the debris hazard/impact zone appears impossible, risk analysis based on established RTS Flight Safety risk equation is done to determine if the risk to the public is within acceptable RCC Standard 321-02 criteria. (Smith, 2002) Collective risk to the general public from any potentially hazardous inert debris (debris impacting the earth with a kinetic energy equal to, or greater than, 1.4 kilogram-meters [11 foot-pounds]) during a single launch would be limited to RCC Standard 321-02 criteria of 3x10⁻⁵. Individual risk from potentially hazardous inert debris would be limited to 1x10⁻⁷.

Post-Launch

Post-launch activities at RTS would generally occur as described in sections 3.3.5 and 4.1.7.

4.3.5.2.2 Targets

Dual target launches would occur from RTS under Alternative 1. Such launches would require construction of new launch pad and modification of an existing GBI Payload Launch Vehicle silo. Otherwise, existing facilities on Meck would be used as previously discussed. Potential impacts from pre-launch, launch, and post-launch activities would be similar to those described for the GBI.

4.3.5.2.3 In-Flight Interceptor Communication System Data Terminal

Under Alternative 1, existing communication systems would be used at current levels discussed under the No Action Alternative. Therefore, no increased impact to health and safety from ongoing operations would be expected.

4.3.5.2.4 Sensors

Use of sensors would continue in accordance with ongoing activities at RTS. For communication link equipment, associated RF emissions are considered to be of sufficiently low power so that there is no exposure hazard. All sensor systems would be sited before operation to ensure that no occupied structures or accessible travel areas are within any hazard area necessitated by RF emissions. Through the use of these procedures, it has been previously determined that proper exposure control would be achieved, and that operation of these systems would not present a significant health and safety hazard (U.S. Army Space and Strategic Defense Command, 1993a).
EXPLANATION

Protection Circle - Based on Payload, Missile, and Launch Azimuth

Source: Tybrin Corporation, 2002b.

Launch Protection Circles

Reagan Test Site

Figure 4.3.5-1
4.3.5.2.5 SBX

Construction

An existing 279- to 465-square-meter (3,000- to 5,000-square-foot) environmentally controlled warehouse space would potentially be required to support SBX operations. Any facility modification required to support the SBX would occur in accordance with existing RTS safety protocol/plans and applicable UES requirements. No adverse effects to health and safety of construction contractors or the public are anticipated.

Operation

The operating area for the SBX would be similar to the existing operating area for GBR-P radar at Kwajalein as described in section 2.1.4.

An EMR/EMI survey and analysis would be conducted by the Joint Spectrum Center that considers HERP, HERF, and HERO. The analysis provides recommendations for sector blanking and safety systems to minimize exposures. The proposed systems would have the appropriate safety exclusion zones established before operation, and warning lights to inform personnel when the system is in operation and emitting EMR. Mechanical and software stops would be used to prevent the main beam from being directed in specified sectors where it may present a hazard.

Potential health and safety hazards associated with operation of similar radars were analyzed in two previous documents: *Ground-Based Radar Family of Radars (GBR) Environmental Assessment* (U.S. Army Program Executive Office Missile Defense, 1993) and *Finding of No Significant Impact* and the *Environmental Assessment for Theater Missile Defense Ground-Based Radar Testing Program at Fort Devens, Massachusetts* (U.S. Army Space and Strategic Defense Command, 1994a). The analysis considered both program operational requirements and restrictions and range-required safety procedures. It was concluded that the required implementation of operational safety procedures, including establishment of controlled areas and limitations in the areas subject to illumination by the radar units, would preclude any potential safety hazard to either the public or workforce from exposure to EMR.

Potential EMR effects of the proposed action are described below and in appendix G.

Radiation Hazards

**Human Exposure.** The analysis method used to evaluate potential effects of RF radiation is the Institute of Electrical and Electronics Engineers Maximum Permissible Exposure Limits (IEEE MPELs), which defines the maximum time-averaged RF power density allowed for uncontrolled human exposure. The MPEL method is independent of body size or tissue density being exposed. EMR hazard zones provide a safety factor 10 times greater than the MPEL. MPELs are capped at 5 mW/cm² for frequencies greater than 1,500 MHz (IEEE C95.1-1999, *Standard for Safety Levels with Respect to Human Exposure to Radio Frequency Electromagnetic Fields, 3 kHz to 300 GHz*). General public exposure is typically limited to one-fifth of the occupational limits.

At X-band frequencies (8,000 MHz-12,000 MHz), the IEEE standard for human exposure is 5.33 mW/cm²-8 mW/cm², respectively. In order for the SBX to have an effect on human health, the
beam operating at full power would have to come in contact with a person and remain on them for 7.5 minutes (at 8,000 MHz) or 11.25 minutes (at 12,000 MHz). With the implementation of software controls on the SBX, there is no radiation hazard area on the deck of the SBX.

**EEDs.** The potential impacts to EEDs from emissions from the XBR are twofold: (1) the EED could be made not to work, or (2) the EED could be inadvertently initiated. The majority of the time, an EED is either installed in its intended application with its leads attached (the presence phase) or is in the shipping/storage phase. Typical EED applications in the presence phase would include fire extinguishers, automotive airbags, a missile attached to the wing of an aircraft, and military aircraft ejection seats. However infrequently, EEDs are sometimes handled without the protection of a storage container (handling/loading phase). Therefore, different susceptibility criteria have been developed for each of these two distinct conditions described above.

As can be seen from table 2.1.4-2, EEDs in the handling/loading phase are substantially more susceptible to EMR hazards; however, main beam illumination on the ground would not occur. As shown in table 2.1.4-2, based upon a grating lobe illumination on the ground from the fully populated SBX, a potential interference distance of 2.3 kilometers (1.4 miles) exists for EEDs in the handling/loading phase. The distances for the 65 percent populated SBX are also shown in the table. It is assumed that the handling/loading of EEDs would not occur when aircraft are airborne. However, main beam illumination of aircraft with EEDs (mainly military aircraft ejection seats) in the presence and shipping phases is possible. There is a potential for EED radiation interference for distances up to 7.5 kilometers (4.6 miles) in the air. Software controls on the SBX and coordination with military and commercial aircraft controllers would be used to ensure that aircraft bearing EEDs are not threatened by main beam interference. Based on the EMR/EMI survey results and coordination with the FAA, DOT, and others, the SBX operating area would be crafted in time and space so as to avoid existing airports, air routes, and airspace users. The SBX operating area would be published on appropriate aeronautical charts to inform pilots of the potential EMI hazard to certain aircraft.

The main beam and side lobes of the SBX could also illuminate EEDs on the ground in the presence/shipping phase. However, the potential radiation hazard would exist only 10 meters (33 feet), in front of the radar, which would be limited to the deck of the SBX. Therefore EEDs in the presence/shipping phase on the ground, including those associated with airbags in vehicles, would not be affected.

**Fuels.** Based upon the threshold of 5,000 mW/cm² from Technical Order 31Z-10-4, the SBX does not present a radiation hazard to fuels because the SBX does not emit radiation levels that exceed 5,000 mW/cm².

**Communications–Electronics Frequency-Related Interference**

In-band frequency interference addressed in this EIS is for the X-band (8,000-12,000 MHz). In-band RF interference occurs when two pieces of communications-electronics equipment are located within the same frequency band. Therefore, equipment with frequencies falling within the X-band would most likely be affected.
Adjacent band RF interference is similar to in-band RF interference. The adjacent bands for the X-band include all frequencies that are within approximately 5 percent of the operating frequency.

Harmonic band interference refers to interference produced in harmonically related receivers or interference caused by sub-harmonically related transmitters. Harmonic frequencies include those frequencies that are integer multiples of the operating frequencies.

Ground-based, airborne, and ship-based systems would be evaluated for in-band, adjacent band, and harmonic band interference during the detailed EMR/EMI survey that is underway. Level 2 surveys are planned to be completed in the summer of 2003.

Communications–Electronics Non-Frequency-Related Interference

Non-frequency-related interference from the SBX to the electromagnetic environment is limited to high-power effects. High-power effects typically occur in receivers that are located in proximity to high power transmitters and may be the result of either antenna-coupled signals or equipment case penetration. The accepted levels for high power effects are 1 mW/cm² for military equipment and 0.1 mW/cm² for civilian equipment. Under proposed SBX operating conditions, full power operation would involve tracking objects in space with the beam pointed up and constantly moving. The beam would not remain stationary for any appreciable period of time, thus the odds of interference from high power effects with any electronic equipment on the ground would be slight, 1/1,000,000 or 0.0001% of the time (roughly 1/10 of a second per day). The effects would not damage any electronic equipment and would last for less than a second, should this occur.

Aircraft/Avionics. The potential exists for EMR emissions from the main beam of the SBX to adversely affect aircraft avionics systems as discussed in section 4.3.2.2.1. The potential health and safety related impacts to aircraft is a reduction in life of the aircraft avionics, not a direct impact to the aircraft operation.

Implementation of RTS operational safety procedures, including establishment of controlled areas and limitations in the areas subject to illumination by the radar units, would preclude any potential safety hazard to either the public or workforce from exposure to EMR. The total amount of radar RF radiation from SBX operation would be approximately 5 to 6 hours per week. The actual operating area of the SBX at the mooring location would be restricted to minimize impacts. SBX operations would be coordinated with the FAA, Coast Guard, and other groups or agencies as appropriate. Therefore, no health and safety impacts to coastal areas, airspace/aircraft, or mariners are anticipated.

4.3.5.3 Alternatives 2 and 3

The Proposed Actions and health and safety impacts would be the same as those described under Alternative 1. Construction and operation of the SBX at RTS for Alternatives 2 and 3 would be the same as those described in section 4.3.5.2.5 for Alternative 1.
4.3.5.4 Cumulative Impacts
The concept of time averaging is important in consideration of the potential cumulative exposures that might occur near operating radars. Because tracking and search radar beams move rapidly, depending on the particular mission or exercise, it is unlikely that environmental exposures would ever consist of continuous, constant values of power density. Rather, almost universally, exposures would be intermittent and, when the radars are transmitting, the electromagnetic fields would be constantly changing in intensity. Thus, the potential for additive, incremental cumulative impacts from EMR exposure is extremely limited. No other projects in the ROI have been identified that would have the potential for incremental, additive cumulative impacts to health and safety. Adherence to RTS safety plans and procedures would preclude potential cumulative impacts to health and safety resulting from the implementation of the GMD ETR.

4.3.5.5 Mitigation Measures
Limitations imposed on the range of azimuth and angles of operation for the SBX and other radar would preclude potential impacts related to health and safety. Mechanical and software stops would be used to control radar operation.

4.3.6 UTILITIES—REAGAN TEST SITE
Appendix B includes a description of utilities issues. A project may have substantial effects on infrastructure and utilities if it increases demand in excess of utility system capacity to the point that substantial expansion would be necessary. Environmental impacts could also result from system deterioration due to improper maintenance or extension of service beyond its useful life.

4.3.6.1 No Action Alternative
Under the No Action Alternative, the GMD ETR would not be established and the SBX would not be developed to support interceptor and target launch scenarios, needed for operationally realistic test conditions. Kwajalein would continue their current operations.

Energy
Daily average demand for electricity at Kwajalein is 13,500 kW. This is 46 percent of the maximum capacity of the electrical service to RTS, or 29,200 kW.

Water
Potable water consumption at Kwajalein is 1.1 million liters (300,000 gallons) per day. This is 64.7 percent of the maximum available amount of potable water, 1.7 million liters (450,000 gallons) per day.

Wastewater
Recent wastewater generation at Kwajalein amounted to approximately 560 liters (148 gallons) per capita per day. This would remain below available capacity.
**Solid Waste**

Solid waste disposal at Kwajalein is handled by landfill and shipping offsite.

### 4.3.6.2 Alternatives 1, 2, and 3

The Proposed Action related to utilities for all alternatives would be PSB support for the SBX while at the mooring location north of Kwajalein.

#### 4.3.6.2.1 SBX

All of the alternatives would include SBX as one of the component of the Proposed Action. The operation of SBX would require BOA and a PSB.

Electrical power requirements for the SBX platform and its various payloads would be approximately 21.8 MW, supplied by six of the eight on-board 3.64-MW generators. The SBX would be self-propelled by four steerable, 3.4-MW electric thrusters that would effectively drive and maneuver the SBX without assistance. During transportation, these retractable, Z-drive thrusters would consume 7 MW, leaving 14.8 MW available for necessary ship-board operations, as well as the XBR.

The SBX has a fuel capacity of approximately 3,100,000 liters (818,000 gallons). The approximate fuel consumption for transit and radar operation is 54,800 liters (14,500 gallons) per day, which would amount to only about 1.8 percent of total fuel capacity daily. There would be a total of 50 crew members, including 20 marine crew and 30 GMD mission support personnel. Additionally, up to 50 people could be accommodated on board on a temporary daytime basis.

At the intervals between GMD test missions, the SBX would either return to a PSB or a nearby mooring location for crew rotations, re-supply, and maintenance activities. If at an adjacent mooring location, three of the generators would still be used: one operating continually while in port for daily ship functions while the remainder would power the half- or fully populated radar 3 hours per day. If necessary, a supply ship would typically deliver food, supplies, repair parts, and fuel from the PSB. In cases wherein pier-side docking is possible, a hookup would be required to provide basic shore power for daily ship functions.

Although the piers at the RTS harbor do not have adequate depth to accommodate the draft of the SBX, the vessel can enter the Kwajalein lagoon and moor in a protected anchorage. An additional re-supply vessel would not be required, as RTS has a full complement of supply and fueling vessels. The mooring site would be approximately 5 to 6 kilometers (3 to 4 miles) north of the RTS harbor. The SBX would enter the lagoon either through South Pass on the west side of the atoll or at Mellu Pass on the north side. Both passes offer sufficient depth to accommodate the vessel. However, Mellu Pass offers a much greater width for maneuverability. Personnel would be ferried to the SBX each day either by watercraft or helicopter. In this case, the self-contained nature of the SBX, particularly its reliance on on-board generators, would ensure that there would be no direct impacts to RTS area utilities.

Existing 900- to 1,500-square-meter (3,000- to 5,000-square-foot) environmentally controlled warehouse space would potentially be required for SBX operations. This would require
accommodations for a maximum of 25 personnel. Ongoing logistics and support operations such as re-supply, fueling, and maintenance and crew/operator training would also occur at the PSB.

Studies have shown an average 189 liters (50 gallons) per capita per day water consumption and 170 liters (45 gallons) per capita per day of wastewater production. Recent figures indicate that in the United States, the per capita generation of municipal solid waste in 1998 was 2 kilograms (4.46 pounds) per capita per day (U.S. Environmental Protection Agency, Region 9, 2002). Average daily demand for water, wastewater, and municipal solid waste for a maximum 25 personnel would be estimated as follows, based on typical usage: 4,725 liters (1,250 gallons) water; 4,259 liters (1,125 gallons) wastewater and 50 kilograms (112 pounds) of solid waste. Any facility modifications being considered would be required to facilitate this level of use, as well as to accommodate any energy demand.

4.3.6.3 Cumulative Impacts
At this time, there are no ongoing or foreseeable future programs/plans identified in the ROI that, when combined with the relatively minor SBX utility requirements, would result in cumulative impacts to utilities. Therefore, no cumulative impacts are anticipated with Alternatives 1, 2, and 3.

4.3.6.4 Mitigation Measures
No mitigation measures would be required or proposed.
4.4 PACIFIC MISSILE RANGE FACILITY

Potential impacts of construction, building modification, and missile launches at PMRF have been addressed in detail in the Strategic Target System EIS, the Restrictive Easement EIS, the PMRF Enhanced Capability EIS, and several program-specific EAs. Based on the prior analyses done and the effects of past target and missile launch activities, the potential impacts related to proposed GMD ETR activities are expected to be minimal, as discussed in the following sections. The existing capability to launch four Strategic Target System target missiles per year would be utilized for GMD. There are no new missile launches proposed from PMRF for the GMD ETR.

4.4.1 AIR QUALITY—PACIFIC MISSILE RANGE FACILITY

4.4.1.1 No Action Alternative

Under the No Action Alternative, there would be no change in current air quality impacts at PMRF. The GMD ETR would not be established and GBI and target launch scenarios would not be tested under operationally realistic conditions. Missile flight test activities would continue at PMRF.

Activities associated with the pre-launch of a target missile include the transportation of targets to the PMRF facilities as well as the assembly of the target. The mobile exhaust emissions due to transportation would be intermittent and would not have a measurable impact to air quality.

The exhaust emissions presented in the PMRF Enhanced Capability EIS (Pacific Missile Range Facility, Barking Sands, 1998) are shown in table 4.4.1-1. As shown, no guidance levels would be exceeded.

The EIS determined that exhaust emissions from Strategic Target System launches would produce 5.1 metric tons (5.6 tons) of aluminum oxide, 3.8 metric tons (4.2 tons) of carbon monoxide, and 1.8 metric tons (1.9 tons) of hydrogen chloride. These levels were not determined to produce short-term exceedences within a previously determined ground hazard area of 3,048 meters (10,000 feet). This area is evacuated of all personnel before any launch. Therefore, no air quality impacts are anticipated for target launches at PMRF.

Activities performed during post target launch would include the removal of all mobile equipment and assets brought to PMRF. The removal could result in small, localized amounts of fugitive dust, which would have a minor impact to air quality. However, this impact would be minimized further through the use of dust suppression methods previously discussed.

4.4.1.2 Alternatives 1, 2, and 3

4.4.1.2.1 Target

Construction

No modifications to existing facilities would be required, and there would be no impact to regional air quality.

Operation

Pre-Launch Activities

Activities associated with the pre-launch of a target missile would be as described under the No Action Alternative.

Launch Activities

Launch activities at PMRF for Alternative 1, 2, or 3 would include launching up to four Strategic Target System targets per year. Potential impacts would be as described under the No Action Alternative.
Post-Launch Activities
Potential impacts would be as described under the No Action Alternative.

4.4.1.2.2 TPS-X

Construction
Installation of the TPS-X radar would require 0.3 hectare (0.8 acre) of previously disturbed land on northern PMRF or at Makaha Ridge. There would be no anticipated impacts to regional air quality.

Operation
The prime power unit for the TPS-X at PMRF is a 1.5-MW generator that provides power to the radar during testing. The generator is assumed to be in operation a maximum of 2,520 hours per year. Potential emissions for the TPS-X are listed in table 4.4.1-3. It is anticipated that operation of the TPS-X would have no adverse impacts on regional air quality at PMRF.

4.4.1.3 Cumulative Impacts
The annual number of closures of the Restrictive Easement for missile launches from PMRF is currently limited to 30 per year. The Proposed Action of up to four target launches per year would be previously analyzed Strategic Target System missiles and would not introduce any new launches to PMRF. No cumulative impacts to air quality have been identified from past launches at PMRF. Missile launches are short-term, discrete events with temporary impacts that are not expected to result in a cumulative impact on air quality.

4.4.1.4 Mitigation Measures
No mitigation measures would be required.
4.4.2 BIOLOGICAL RESOURCES—PACIFIC MISSILE RANGE FACILITY

4.4.2.1 No Action Alternative

If the GMD ETR is not established, PMRF would still continue to be operated as an LF and would support single launches of target missiles for a less robust GMD program. Missile flight test activities would continue at PMRF. Impacts from launches of Strategic Target System missiles are described below.

Construction

Vegetation

Only minor site preparation activities are required for target launches. The site(s) for the launch activities are previously cleared, improved locations. Any spill or release of hazardous material would likely be restricted to a small, localized area near the source. SOPs and spill plans reduce any potential impact to vegetation. Negligible impacts to vegetation are anticipated.

Threatened and Endangered Plant Species. No adverse impacts are anticipated to the Ohai and Lau‘ehu habitat since no ground-disturbing activities would be required.

Wildlife

Disturbance to wildlife, including migratory birds, from minor site preparation activities and increased personnel would be short-term and is not expected to have a lasting impact or a measurable negative effect.

Any spill or release would likely be restricted to a small, localized area near the source. SOPs and spill plans would reduce any potential impact to wildlife in the vicinity of the spill.

Threatened and Endangered Wildlife Species. No impacts from site preparation activities are expected to the Newell’s Townsend’s shearwater, Hawaiian dark-rumped petrel, Hawaiian (American) coot, Hawaiian black-necked stilt, Hawaiian common moorhen, and Hawaiian duck, which have been observed in the drainage ditches and ponds on PMRF. Reflection from outdoor lighting could disorient the Newell’s Townsend’s shearwater, which may fly over PMRF at night (mainly between April and November). Any outdoor lighting associated with site preparation activities is properly shielded, following USFWS guidelines, to minimize reflection and impact to these birds.

Site preparation activities and personnel presence are not anticipated to affect the Hawaiian hoary bat, which has been observed feeding offshore of Polihale State Park north of the Strategic Target System launch pad. Site preparation activities are also not likely to affect marine species such as the Hawaiian monk seal and sea turtles since areas used are not within areas used by the monk seal or sea turtles. Any observed green sea turtle nests near the launch pad would be noted and avoided.
Environmentally Sensitive Habitat
No adverse impacts to the coastal dune systems, marine sanctuary, coral reefs, or critical habitats are anticipated as a result of any minor site preparation activities.

Operation
Up to four Strategic Target System missiles per year may currently be launched from the KTF at PMRF. The current missile trajectories are toward the RTS BOA and toward the BOA off the northwest coast of North America. The RTS trajectory has been successfully used four times in the last 10 years.

Vegetation
Normal launch activities are not expected to impact vegetation. Analysis provided in the Strategic Target System EIS (U.S. Army Strategic Defense Command, 1992) concluded that although vegetation near the Strategic Target System launch pad could suffer some temporary distress from the heat generated at launch and from hydrogen chloride or aluminum oxide emissions, there is no evidence of any long-term adverse effect on vegetation from two decades of launches at PMRF. The continued presence of the adder’s tongue, a species removed from the list of federal candidate species, indicates that emissions from Strategic Target System missiles have not had a significant impact on sensitive vegetative species.

Threatened and Endangered Plant Species. The possibility of a spill or other accident involving hazardous materials impacting Ohai and Lau’ehu habitat is considered remote since these plants have only been observed north of PMRF. Any spill or release of hazardous material would likely be restricted to a small, localized area near the source and would be cleaned up in accordance with PMRF’s spill plan.

Wildlife
No substantial impacts to threatened and endangered species from existing EMR sources on PMRF have been identified.

Noise. Disturbance to wildlife from the launches is brief and is not expected to have a lasting impact nor a measurable negative effect on migratory bird populations. Wildlife such as waterfowl would quickly resume feeding and other normal behavior patterns after a launch is completed.

Potential noise effects on wildlife can be categorized as auditory and non-auditory. Auditory effects would consist of direct physical changes, such as eardrum rupture or TTS. Non-auditory effects could include stress, behavioral changes, and interference with mating or foraging success. The effects of noise on wildlife vary from serious to no effect in different species and situations. Behavioral responses to noise also vary from startling to retreat from favorable habitat. Animals can also be very sensitive to sounds in some situations and very insensitive to the same sounds in other situations. (Larkin, 1996) Informal observation at several LFs indicates the increased presence of personnel immediately before a launch tends to cause birds and other mobile species of wildlife to temporarily leave the area that would be subject to the highest level of launch noise. Therefore, no direct physical auditory impacts are anticipated. Wildlife is known to exhibit a startle effect when exposed to short-term noise impacts, such as
the launch of a target missile. Birds usually show signs of disturbance, such as fluttering of wings, when the noise occurs, but quickly return to normal behavior after the event. Video camera observations of a wood stork colony located 0.8 kilometer (0.5 mile) south of the Space Shuttle launch pad at Kennedy Space Center showed the birds flew south away from the noise source and started returning within 2 minutes, with a majority of individuals returning in 6 minutes (National Aeronautics and Space Administration, John F. Kennedy Space Center, 1997).

A rookery at Kennedy Space Center used by wood storks and other species of wading birds is located approximately 750 meters (2,461 feet) from a Shuttle launch pad. This rookery continues to be used successfully, even though it has received peak noise levels of up to approximately 138 dB. (American Institute of Aeronautics and Astronautics, 1993) As mentioned above, monitoring studies of birds during the breeding season indicate that adults respond to Space Shuttle noise by flying away from the nest, but they return within 2 to 4 minutes. Birds within 250 meters (820 feet) of Titan launch complexes at Cape Canaveral Air Station have shown no mortality or reduction in habitat use. Titan IV vehicles produce noise levels of approximately 170 dB in the immediate vicinity of the launch pad. This attenuates to 125 dB at a distance of 3 kilometers (2 miles) within about 30 seconds following launch. (U.S. Department of the Air Force, 1990b)

No evidence has indicated that serious injuries would result, and no long-term adverse effects are anticipated. The brief noise peaks produced by the missiles such as the Strategic Target System are comparable to levels produced by close range thunder (120 dB to 140 dB peak), and there is no species known to be susceptible to hearing damage following intermittent exposure to this common noise source (U.S. Department of the Air Force, 2001).

**Emissions.** Hydrogen chloride, which is emitted during missile launches, is known to affect wildlife. However, results of monitoring conducted following a Strategic Target System launch from the KTF at PMRF indicated little effect upon wildlife due to the low-level, short-term hydrogen chloride emissions (U.S. Army Space and Strategic Defense Command, 1993a). The program included marine surveys of representative birds and mammals for both pre-launch and post-launch conditions. Studies on representative birds and mammals reviewed in the Final EIS for the Strategic Target System (U.S. Army Strategic Defense Command, 1992) also indicated that low-level, short-term exposure to hydrogen chloride would not adversely affect threatened or endangered species or other wildlife. Aluminum oxide and hydrogen chloride do not bioaccumulate; therefore, no indirect effects to the food chain are anticipated.

An early flight termination or mishap could result in debris impact along the flight corridor, which may temporarily impact fishing activities in the immediate area. Due to the small amount of propellant involved and the few number of launches, ongoing launches are not anticipated to adversely affect marine resources. Unburned solid fuel is hard and rubber-like, and any ammonium perchlorate would dissolve slowly out of the rubber-like binder, producing ammonia and chlorine that would disperse into the marine waters. Were hazardous materials to leach out of the intercept debris, the great volume of water in the ocean would dilute the contaminant to acceptable levels. The solid fuel’s aluminum oxide is insoluble; in addition, as the fuel slowly dissolves, its outer layers become spongy, further retarding dissolution. Thus, no toxic levels of ammonia, chlorine, or aluminum would be expected. A recent study conducted for the U.S. Air Force (Lang, et al., 2001) measured the amount of perchlorate lost from solid propellant samples immersed in fresh and salt water. From the measurement of the concentration of the
perchlorate ion in solution, the mass fraction loss of the propellant sample due to perchlorate leaching was calculated. The results are presented in the KLC Water Resources section, table 4.1.14-2. As shown in the table, it would take approximately 270 days for 90 percent of the perchlorate to leach out of solid propellant that lands in the ocean (at 29 °C [84°F]). The perchlorate would be expected to be diluted as it mixes with the surrounding water. The potential ingestion of toxins by fish species, which may be used for food sources, would be remote because of the diluting effect of the ocean water and the relatively small area that would be affected.

**Essential Fish Habitat.** The potential impact to Essential Fish Habitat from nominal launch activities would mainly be from spent boosters and missile debris to waters off the coast within the Temporary Operating Area. Although spent boosters and intercept debris could affect any species close to the surface, the number of individuals injured or killed would not likely affect overall species’ populations. The majority of propellant would be expended before booster drop and impact and thus only trace amounts of propellant would be left, which would minimize the potential for toxic effects. (U.S. Department of the Air Force, 2001)

In the unlikely event of a launch mishap, scattered pieces of burning propellant could enter coastal water and potentially affect Essential Fish Habitat. Concentrations of toxic materials would be highest in this shallow water and have a greater chance of being ingested by feeding animals. However, the potential for a launch mishap is relatively slight, and in most cases the errant missile would be moving at a rapid rate such that pieces of propellant and other toxic debris would strike the water further downrange. The debris would also be widely scattered, which would reduce the possibility of ingestion. As mentioned above, the number of individuals injured or killed would not likely affect overall species’ populations. (U.S. Department of the Air Force, 2001)

**Threatened and Endangered Wildlife Species.** Impacts from launch noise to the Newell’s Townsend’s shearwater, Hawaiian dark-rumped petrel, Hawaiian (American) coot, Hawaiian black-necked stilt, Hawaiian common moorhen, and Hawaiian duck would be limited to startle or flushing reactions as discussed above. Reflection from outdoor lighting could disorient the Newell’s Townsend’s shearwater; however, any outdoor lighting associated with launch activities would be properly shielded, following USFWS guidelines. Existing range radars and other instrumentation that would be used at PMRF are discussed in section 2.3.1.4. No substantial impacts to threatened and endangered species from existing EMR sources on PMRF have been identified.

No adverse impacts are anticipated to the Hawaiian hoary bat, which has been observed feeding offshore of Polihale State Park, north of the project area. The likelihood that debris from a spent booster or terminated launch would strike a Hawaiian monk seal is considered remote since the waters adjacent to PMRF are used infrequently by this species. The launch would be delayed if monk seals are observed in the launch safety zone or beach portion of the Launch Hazard Area. Green sea turtles nests have been observed in the sand near the Nohili Ditch. Green sea turtles lay eggs only at night, once every 2 to 4 years. Thus, the potential for debris to strike a green sea turtle near or on shore is remote. Access to green sea turtle nesting beaches would be restricted.
Environmentally Sensitive Habitat

The Hawaiian Islands Humpback Whale National Marine Sanctuary FEIS and Management Plan (U.S. Department of Commerce, National Oceanic and Atmospheric Administration and State of Hawaii, Office of Planning, 1997) recognizes that PMRF plays an important role in national defense training. The EIS includes missile launches as one of the DoD activities that currently occurs within the sanctuary boundaries. The ongoing missile launches would have impacts within the parameters of ongoing missile programs.

According to analysis provided in the PMRF Enhanced Capability EIS, debris from shore-based missile launch programs is not expected to produce any measurable impacts on benthic (sea floor) resources beyond those currently experienced during natural conditions associated with storms.

4.4.2.2 Alternatives 1, 2, and 3

Alternatives 1, 2, and 3 would require the use of existing launch pads, Missile Assembly Building, missile storage facility, range radars, and maintenance and storage facility to support target missile launches.

4.4.2.2.1 Targets

Site Preparation Activities

Site preparation activities at PMRF for Alternative 1, 2, or 3 would include launching up to four Strategic Target System targets per year. Potential impacts would be as described under the No Action Alternative.

Launch Activities

Launch activities at PMRF for Alternative 1, 2, or 3 would include launching up to four Strategic Target System targets per year. Potential impacts would be as described under the No Action Alternative.

Post-Launch Activities

Potential impacts would be as described under the No Action Alternative.

4.4.2.2.2 TPS-X Radar

Construction

Vegetation

Installation of the TPS-X radar would require 0.3 hectare (0.8 acre) of previously disturbed land on northern PMRF or at Makaha Ridge. No impacts to vegetation are anticipated.

Threatened and Endangered Plant Species. No impacts to potential Ohai or Lau‘ehu habitat on PMRF or to the endangered dwarf iliau found within the Makaha Ridge complex are anticipated since no ground-disturbing activities would be required.
Wildlife
Disturbance to wildlife, including migratory birds, from the minor site preparation activities and temporary increase in personnel in the area would be short-term and is not expected to have a lasting impact or measurable negative effect.

Threatened and Endangered Wildlife Species. Site preparation activities could potentially startle any Newell's Townsend's shearwater, Hawaiian dark-rumped petrel, Hawaiian (American) coot, Hawaiian black-necked stilt, Hawaiian common moorhen, or Hawaiian duck, which could be in the drainage ditches adjacent to the TPS-X radar site on northern PMRF, or the Hawaiian goose population present in the Makaha Ridge area. This disturbance would be brief and is not expected to have a lasting impact nor a measurable negative effect on migratory bird populations. Wildlife such as waterfowl would quickly resume feeding and other normal behavior patterns. Reflection from outdoor lighting could disorient the Newell's Townsend's shearwater, which may fly over PMRF at night (mainly between April and November). Any outdoor lighting associated with construction activities and permanent structures would be properly shielded, following USFWS guidelines to minimize reflection and impact to these birds.

Site preparation activities and personnel presence are not anticipated to affect the Hawaiian hoary bat, which has been observed feeding offshore north of the Nohili Ditch. Site preparation activities are also not likely to affect marine species such as the Hawaiian monk seal and sea turtles since these animals are normally offshore or on the beach seaward of the berm. Any observed green sea turtle nests near the northern PMRF site would be noted and avoided.

Environmentally Sensitive Habitat
No wetlands or other sensitive habitat would be disturbed during installation of the TPS-X radar.

Operation
Vegetation
Impermeable ground covering material and spill containment berms would be placed for containment of fuel during fueling operations of the Prime Power Unit and Cooling Equipment Unit system hook-up. Spill control procedures would be established in cooperation with the host installation, and spill control kits would be present at the site in the unlikely event of a fuel leak or spill.

Threatened and Endangered Plant Species. No impacts to potential Ohai or Lau'eahu habitat on PMRF or to the endangered dwarf iliau found within the Makaha Ridge complex are anticipated from operation of the TPS-X radar since no ground-disturbing activities would be required.

Wildlife
The Prime Power Unit is a self-contained trailer with a noise-dampening shroud that would minimize the potential for diesel generator noise impacts.

As discussed in the KLC section, the power densities emitted from the TPS-X radar are unlikely to cause any biological effects in animals or birds. The TPS-X radar is not expected to radiate lower than 5 degrees, which would preclude EMR impacts to terrestrial species from either
operation of the TPS-X radar during flight tests or later during proposed tactical testing. Impacts to wildlife on PMRF or Makaha Ridge would be similar to those discussed above in the KLC TPS-X radar section.

**Threatened and Endangered Wildlife Species.** There have been no reports of birds being affected by EMR from the existing sensors located in the Makaha Ridge complex. Impacts to the threatened and endangered birds on and offshore of PMRF would be similar to those discussed above in section 4.1.3.2.5. The protection provided by the restricted access, and grassy habitat within Makaha Ridge would continue to have a positive effect on the small population of Hawaiian goose (Pacific Missile Range Facility, 2000). Impacts to threatened and endangered marine species offshore of PMRF would be similar to those discussed above in section 4.1.3.2.5.

*Environmentally Sensitive Habitat*

No wetlands or other sensitive habitat would be adversely affected by operation of the TPS-X radar.

### 4.4.2.3 Cumulative Impacts

No cumulative impacts to biological resources have been identified from past launches at PMRF. Combined activities would be performed at different times and locations and therefore, no substantial cumulative impacts to biological resources are anticipated at PMRF.

### 4.4.2.4 Mitigation Measures

No biological resources mitigation measures are proposed for GMD ETR activities.

### 4.4.3 HAZARDOUS MATERIALS AND HAZARDOUS WASTE—PACIFIC MISSILE RANGE FACILITY

This section addresses potential impacts that could result from the storage and use of hazardous materials and the generation and disposal of hazardous waste associated with launch operations from PMRF, and construction required to support GMD launch operations. Pollution prevention, recycling, waste minimization, IRPs, USTs, ASTs, asbestos, lead-based paint, and PCBs have been considered. Potential impacts from launch activities are addressed under each alternative as applicable.

#### 4.4.3.1 No Action Alternative

Implementation of the No Action Alternative would result in the ongoing launch of Strategic Target System missiles from PMRF. Use of PMRF for flight preparation and testing has been previously analyzed in the PMRF Enhanced Capability Final EIS (Pacific Missile Range Facility, Barking Sands, 1998) and the North Pacific Targets Program EA (U.S. Army Space and Missile Defense Command, 2001b). These documents concluded that adherence to PMRF standard SOPs as well as federal, state and local regulations would significantly reduce any impact from hazardous materials handling or waste generation. Impacts from launches of Strategic Target System missiles would be as described below.
Pre-Launch Activities
All elements of the Strategic Target System would be transported, handled and stored at PMRF in accordance with applicable federal, state, U.S. Army and U.S. Air Force regulations and standard range SOPs.

Launch Activities
Potentially hazardous materials (external to those preloaded into the missiles) to be used would be fuel required for electrical power generators, coating, sealants and solvents needed for launch and launch preparation. The types of hazardous materials used and hazardous waste generated would be managed in accordance with existing PMRF procedures and requirements. These procedures and requirements conform to federal and State of Hawaii laws and regulations. Best practices, lessons learned, and expectations indicated in the interim guidance DoD 5000.2R would be incorporated into design and construction plans.

In addition, the PMRF Fire Department and Hazardous Materials Response Team are trained in the appropriate procedures to handle the materials associated with Strategic Target System launches should a mishap occur. All personnel involved in these operations would wear protective clothing and receive specialized training in spill containment and cleanup.

During launches there is the potential for a mishap to occur resulting in potentially hazardous missile debris and propellants falling within the Ground Hazard Area. As addressed for previous launch programs on PMRF, the hazardous materials that result from a flight termination would be cleaned up and any contaminated areas remediated. All hazardous waste generated in such a mishap would be disposed of in accordance with appropriate state and federal regulations.

Post-Flight Test Activities
Specific restoration actions, if necessary, would be determined on a case-by-case basis in coordination with the procedures of the Facility Services Division of Hazardous Materials.

4.4.3.2 Alternatives 1, 2, and 3

4.4.3.2.1 Target
Alternatives 1, 2, and 3 would involve single Strategic Target System launches from PMRF, as described in the No Action Alternative. This is a routine activity for PMRF and is included in current hazardous materials and hazardous waste management plans. No additional activities would be performed, no new potentially hazardous materials would be used, and no significant increase in the amount of hazardous waste currently generated would be expected to occur. Hazardous materials used and hazardous wastes generated would continue to be handled in accordance with existing laws and regulations governing the transportation and disposal of these materials.

4.4.3.2.2 TPS-X Radar
Construction
Alternatives 1, 2, and 3 would require the set up of the TPS-X radar and associated equipment. The site would include a gravel pad, concrete pad, security fencing and utilities/communications
installation. Generation of potential hazardous waste (e.g., corrosion control coatings, adhesives, and sealants) would be minimal. Management of hazardous materials and hazardous waste would be performed in accordance with PMRF requirements and would not significantly impact existing PMRF hazardous materials and hazardous waste management procedures.

**Operation**

Operation of the TPS-X would have little effect on hazardous waste and hazardous materials management. A 3,785-liter (1,000-gallon) AST would be used for diesel fuel for the backup generator.

### 4.4.3.3 Cumulative Impacts

Adherence to the hazardous materials and waste management systems on PMRF would preclude the potential accumulation of hazardous materials or waste. The base has implemented an emergency response procedure that would aid in the evaluation and cleanup of any hazardous materials released. The Proposed Action is equivalent to the No Action Alternative and is not expected to result in cumulative hazardous materials and hazardous waste impacts on PMRF.

### 4.4.3.4 Mitigation Measures

No hazardous materials/hazardous waste management mitigation measures are proposed for GMD ETR activities.

### 4.4.4 HEALTH AND SAFETY—PACIFIC MISSILE RANGE FACILITY

#### 4.4.4.1 No Action Alternative

Under the No Action Alternative, Strategic Target System launches would continue at PMRF. Potential health and safety issues associated with Strategic Target System launches include pre-launch, launch, and post-launch activities. Use of PMRF for flight preparation and testing and potential health and safety issues have been previously analyzed in the PMRF EIS and North Pacific Targets Program EA. These documents concluded that PMRF takes every reasonable precaution during the planning and execution of these operations to prevent injury to human life or property. Therefore, no increased risk to health and safety is expected as a result of implementing this alternative. Impacts from launches of Strategic Target System missiles would be as described below.

**Pre-Launch Activities**

Missiles and support equipment may arrive at Pearl Harbor before final shipment to PMRF. Equipment would be available at Pearl Harbor for the loading and unloading of missiles. Storage areas would be available for the temporary storage of any hazardous materials. Missiles and support equipment would be transported by ship to Nawiliwili Harbor, then by DoD/DOT-approved over the road carrier truck to PMRF. Missiles and support equipment may also be transported directly to PMRF by aircraft. Applicable state and federal regulations and range safety plans and procedures are followed in transporting and handling potentially explosive ordnance and hazardous materials. Missile components, including any propellant, are transported in DOT and military designed and approved shipping containers.
The type of protection afforded by shipping containers is sufficient to protect solid rocket motors from receiving the shock required to cause an explosion. In the event of a transportation accident, it is more likely that the solid propellants would burn. The solid propellants would release exhaust components, specifically hydrogen chloride, which would irritate the eyes and skin of persons in the nearby area. Such an accident would not likely occur given the in-place safety procedures used by PMRF during transportation and handling of missile components. ESQDs would be established around transportation corridors.

On arrival at PMRF, support equipment is placed in secure storage until assembly and launch preparation. ESQDs are established around ordnance storage and Missile Assembly Buildings. Access to storage and support facilities is limited to trained and authorized PMRF/mission critical personnel.

Launch Activities

A pre-launch accident on the launcher or in the assembly building would be characterized by either an explosion and/or detonation of missile propellants or burning of the propellants without an explosion or detonation. An ESQD surrounding the launcher would be calculated based on the equivalent explosive force of all propellant and pyrotechnic materials contained on the flight vehicle. Areas outside the ESQD zone provide acceptable protection and require that areas inside the ESQD zone be cleared of non-mission-essential personnel. The ESQD would vary from missile to missile. Fire suppression, hazardous materials emergency response, and emergency medical teams would routinely be provided during the actual launch operations.

Potential health and safety impacts associated with launch operations could occur as a result of inhalation of exhaust products associated with normal operation; impact hazard associated with a launch anomaly (explosion, crash, flight termination); and inhalation hazards from an abnormal launch (fire, crash, flight termination). The primary method for preventing potential adverse safety and health effects associated with these occurrences involves the physical isolation of the area immediately surrounding the launch site, before launch. At no time shall individuals of the public be exposed to a probability of fatality greater than 1 in 10 million for any single mission and 1 in 1 million on an annual basis. This standard maximum risk to the public is less on an annual basis than the risks from accidents occurring in the home or in public. (Range Commanders Council, Range Safety Group, 2002) Before launch, safety clearance areas would be established to provide an area where all potentially hazardous debris from a launch anomaly would be contained. Ground and range safety areas would be determined to protect the general public and private property against potential launch mishap. Non-mission-essential personnel would be excluded from the ground safety area and Launch Hazard Area during launch operations. Personnel working within the Launch Hazard Area would be protected in bunkers or behind berms. Numerous factors determine the shape and dimensions of the ground safety area and Launch Hazard Area, including the following:

- Size and flight characteristics of the missile
- Individual flight profile for each exercise or flight test
- Reaction time between recognition of a flight malfunction and the decision to terminate flight
The ground safety area size is determined by simulating the missile’s capability to travel off course in any direction (360 degrees) from the launch point for a specified period of time. Five seconds would be the commonly used time period, but this period can be modified based on local range procedures, capabilities, and mission requirements. The analysis assumes that at the end of the time period, the missile flight would be terminated by the Flight Termination System, and the associated debris would fall to the ground or sea. The outer perimeter within which this potentially hazardous debris could fall, in any direction, factoring in prevailing wind conditions, defines the boundaries of the ground safety area.

Data processed by ground-based or onboard missile computer systems is used to recognize malfunctions and terminate missile flight. The Safety Officer continuously monitors the flight and would always retain the capability to terminate the flight, if necessary. For a typical aerial target drone, the nominal ground safety area for launches extends to a radius of up to approximately 366 meters (1,200 feet). For ballistic missiles, the nominal ground hazard area is 610 meters (2,000 feet) for unguided rail-launched targets and a modified 3,048 meters (10,000 feet) for larger stool-launch guided missile targets (Pacific Missile Range Facility, Barking Sands, 1998). The Range Safety Officer would use computer models to determine actual ground safety area dimensions and safety procedures for each target missile flight, based on the above factors.

To accommodate launches of larger missiles, PMRF has an existing restrictive easement for a ground safety area of a modified 3,048 meters (10,000 feet) that extends beyond the PMRF property boundary. This restrictive easement is used to set up the Launch Hazard Area to ensure public safety during a launch. The use of the restrictive easement until 2030 was analyzed in the PMRF Enhanced Capability EIS. As described in the PMRF Enhanced Capability EIS, launches from KTF toward the BOA near USAKA/Kwajalein Missile Range used the launch azimuth of 280 degrees to avoid overflight of the Island of Niihau. The North Pacific Targets Program EA analyzed launches for payload impact in the BOA off the northwest coast of North America with initial launch azimuths of 310 to 360 degrees. The Range Safety Officer would use computer models to determine actual ground safety area dimensions and safety procedures for each target missile flight.

In addition to the ground safety area, a Launch Hazard Area is established over water where any potentially hazardous debris from a flight termination or missile stage could fall. The Launch Hazard Area would be determined for each type of flight test, taking into account the same parameters used in determining the ground safety area. Before launch PMRF would issue NOTAMs and NOTMARs. Area surveillance and clearance of the Launch Hazard Area is provided by PMRF aircraft and marine vessels, as part of their routine operations. To further minimize potential launch-associated hazards, emergency response teams are on standby during launch operations for fire suppression, hazardous materials collection and removal, and medical response as necessary.

The potential health and safety impact resulting from a nominal launch includes the inhalation of exhaust products during the first few seconds of the launch operation. Concentrations of exhaust products are expected to be below applicable health-based standards by the time the exhaust plume reaches the boundary of the ground safety area or Launch Hazard Area. Thus the public would not be exposed to concentrations exceeding exposure limits. Modeling conducted for previous Strategic Target System launches has determined that a normal launch would not endanger public health or safety in the vicinity/area of PMRF.
Post-Launch Activities
Potentially hazardous debris would impact the ground or open ocean should a flight termination occur. Debris would primarily consist of metals, solid propellant, and batteries. Much of any hazardous material in the missile would be consumed in launch anomaly. Potentially hazardous debris would be recovered from the ground and disposed of in accordance with applicable state, federal, and range hazardous waste regulations and operating procedures. Most liquid propellant potentially used in upper stages would be consumed in flight termination and would not likely affect health and safety.

4.4.4.2 Alternatives 1, 2, and 3

4.4.4.2.1 Target
Single target launches would occur from PMRF under Alternatives 1, 2, and 3. All launch activities would be conducted as previously analyzed in the PMRF EIS, Strategic Target System EIS, North Pacific Target Program EA, and in compliance with federal, state, local and, if applicable, international health and safety requirements and strict PMRF SOPs. Therefore, no increased risk to health and safety would be expected as a result of selecting these alternatives.

4.4.4.2.2 TPS-X Radar
Construction
The potential TPS-X locations would be northern PMRF or at Makaha Ridge. Construction activities would be accomplished in accordance with the safety plans and procedures described in section 4.1.7.2. No adverse effects to health and safety are expected from construction of the TPS-X pad.

Operation
EMR hazard zones would be established within the beam's tracking space and near emitter equipment. The potential interference distances are shown in figure 2.3.1-8. A visual survey of the area would be conducted to verify that all personnel are outside the hazard zone prior to startup. Personnel may not enter these hazard zones while the radar is in operation. The radar is prevented from illuminating in a designated cutoff zone, in which operators and all other system elements would be located. Potential safety consequences associated with radar interference with other electronic and emitter units (flight navigation systems, tracking radars, etc.) would also examined prior to startup. Adherence to PMRF, FAA, and DoD safety procedures relative to radar operations would preclude significant impact to health and safety.

4.4.4.3 Cumulative Impacts
Potentially hazardous operations at PMRF would continue at levels similar to current conditions. No cumulative impact to the public health and safety would be expected from exposure to EMR emission, hazardous air pollutants, hazardous materials or hazardous waste operations at PMRF. Any long-term exposures to on-base personnel would be minimized due to the strict adherence to regulatory control when handling materials. Based on the PMRF SOPs and other activities in the area, there is minimal potential for cumulative health and safety risk to the public from operations at PMRF. The proposed number of single target launches expected under
Alternatives 1, 2, and 3 would not represent an increase over current conditions and therefore would not increase potential public health and safety risk.

4.4.4 Mitigation Measures
No health and safety mitigation measures are proposed for GMD ETR activities.

4.4.5 SOCIOECONOMICS—PACIFIC MISSILE RANGE FACILITY

4.4.5.1 No Action Alternative
Under the No Action Alternative, Strategic Target System launches would continue at PMRF. The use of PMRF for flight preparation and testing and potential socioeconomic issues have been previously analyzed in the PMRF EIS and North Pacific Targets Program EA. These documents concluded that there would be no significant impacts to socioeconomics from the launch of four Strategic Target System missiles per year. Impacts from launches of Strategic Target System missiles would be as described below for the Proposed Action.

4.4.5.2 Alternatives 1, 2, and 3

4.4.5.2.1 Target
Under the implementation of Alternatives 1, 2, and 3, PMRF would be used as a launch site for single Strategic Target System vehicles; the impacts from the launch of these targets have previously been analyzed in the PMRF Enhanced Capability Final EIS (Pacific Missile Range Facility, Barking Sands, 1998) and in the North Pacific Targets EA (U.S. Army Space and Missile Defense Command, 2001b). Potential impacts would be the same as described for the No Action Alternative.

4.4.5.2.2 Sensors
Under the implementation of each alternative, PMRF would be used as a supporting facility for mid-range telemetry during both target and GBI launches and intercepts. This could include the use of existing tracking and surveillance radars, telemetry receivers and recorders, and communications systems. Mobile telemetry systems could also be used at PMRF or at Makaha Ridge.

4.4.5.2.3 Cumulative Impacts
The Proposed Action is equivalent to the No Action Alternative and is not expected to result in cumulative socioeconomic impacts at PMRF.

4.4.5.2.4 Mitigation Measures
No socioeconomic mitigation measures are proposed for GMD ETR activities.
4.5  VANDENBERG AIR FORCE BASE

4.5.1  AIR QUALITY—VANDENBERG AIR FORCE BASE

4.5.1.1  No Action Alternative

Under the No Action Alternative, launch activities would continue at Vandenberg AFB, although
the GMD ETR would not be established and GBI and target launch scenarios would not be
tested under operationally realistic conditions.

Table 4.5.1-1 lists propellant information for the Titan IV, Delta II and IV, and Atlas V, common
launch vehicles at Vandenberg AFB. The exhaust emissions presented in the EIS for the
Evolved Expendable Launch Vehicle Program (U.S. Department of the Air Force, 1998a) and
the Supplemental EIS for the Evolved Expendable Launch Vehicle (U.S. Department of the Air
Force, 2000) for these vehicles are shown in table 4.5.1-2.

ppm = parts per million
mg/m³ = milligrams per cubic meters
NA = Not available
These vehicle emissions are typical of those launched from Vandenberg AFB. The U.S. Air Force standard for hydrogen chloride is 10 ppm for an instantaneous level. The OSHA standard for aluminum oxide is 5 milligrams per cubic meter (mg/m³).

The EELV EIS and Supplemental EIS concluded that up to an additional nine launches per year would not exceed NAAQS, state AAQS, U.S. Air Force, or OSHA standards. Current range activities would continue. Launches from Vandenberg AFB are limited to 30 annually (10 military launches and 20 space launches), including current launching of the Peacekeeper, BV, targets and Minuteman II. Table 4.5.1-3 lists annual emissions from Vandenberg AFB and Santa Barbara County.

Source: U.S. Department of the Air Force, 2000

**Upper Atmosphere**

No specific requirements are used for regulating emissions to the upper atmosphere. The Supplemental EELV EIS states launches that would result in local and global impacts to the upper atmosphere. The passage of a lift vehicle through the stratosphere has been shown to cause a temporary, local decrease in a so-called “hole” in the ozone layer; however, these holes only exist for a matter of minutes to hours. According to the EELV EIS and Supplemental EELV EIS, current launches would not result in significant impacts to the upper atmosphere.

4.5.1.2 Alternative 1

4.5.1.2.1 Targets

Construction

Construction activities associated with target facilities at Vandenberg AFB would include interior and software modifications to existing facilities. Therefore, there would be no increase to regional air quality emissions at Vandenberg AFB due to construction.

Operation

Santa Barbara County is in attainment for all air quality standards except the state ozone and PM-10 standards. Santa Barbara County has recently met the federal standard for ozone and is in the process of being redesignated by the EPA as being in attainment. Alternative 1 would not substantially impact the regional air quality within the Santa Barbara Air Basin.
Pre-Launch Activities

Vandenberg AFB complies with the Santa Barbara County Air Pollution Control District rules and regulations listed below. Alternative 1 would comply with these and any other applicable rules.

- Rule 317, Organic Solvents, provides limits to any solvent materials used in the project.
- Rule 323, Architectural Coatings, provides for coating materials applied to an architectural structure.
- Rule 330, Surface Coating of Metal Parts and Products, applies if metal parts are coated on base before construction.
- Rule 353, Adhesives and Sealants, applies if adhesives, adhesive bonding primers, adhesive primers, sealants, sealant primers, or any other primers are used during the project unless specifically exempted by this rule.
- Only California Air Resources Board-certified blasting medium would be permitted if abrasive blasting were used.
- Any portable equipment powered by an internal combustion engine of 20 British horsepower or higher used in this project must be registered in the California State-wide Portable Equipment Registration Program or have a valid Santa Barbara County Air Pollution Control District Permit to operate. (Vandenberg Air Force Base, 2001)

Pre-launch activities associated with Alternative 1 at Vandenberg AFB would include the transportation of the target. The mobile emissions resulting from this transportation would be intermittent and would not have a measurable impact to regional air quality.

If used as a target, the fourth stage of a Peacekeeper target would utilize a single liquid propellant and require onsite fueling. Although total vapor emissions can vary depending on the propellant transfer equipment used and how it is assembled, it is anticipated that only very small amounts (approximately 10 grams [0.4 ounce]) of vapors would be released to the atmosphere during the transfer operation. It is not anticipated that normal fueling operations would impact air quality.

It is unlikely that a propellant release larger than that described above would occur at Vandenberg AFB. However, if such an accidental release were to occur, it would most likely occur during fueling. A reasonable scenario would involve failure of the transfer equipment or valves. The analysis assumes a leak contained over a 3-minute period that releases up to 17 liters (4.5 gallons) of hydrazine fuel. Analysis indicated no potential exceedances of the Immediately Dangerous to Life and Health (IDLH) health standard of 50 ppm. The low likelihood of such an occurrence and the implementation of approved emergency response plans would limit the impact of such a release.

Emergency generators would supply backup power to target facilities with offsite commercial power sources providing primary power. The emergency backup generators would be operated under appropriate permits and restrictions. Portable generators that operate less than 200 hours per year currently do not require permits; however, Santa Barbara County Air Pollution
Control District is in process of changing permitting applicability which could require New Source Review permitting, emission offsets, or emission control equipment.

Launch Activities

Proposed target missiles could consist of one of several types of missiles including Strategic Target System, Minuteman II target, Peacekeeper target, and Trident I (C4) target. Table 4.5.1-4 lists missile propellant information and table 4.5.1-5 lists emission constituents during Stage I for each proposed missile. In Alternative 1, a total of five target launches per year would be anticipated at Vandenberg over the duration of the program.

NA = Not available
Emissions from dual target launches were modeled using the Peacekeeper Target, as it is the largest of the proposed target vehicles. Dual emissions were modeled using OBODM to determine levels of hydrogen chloride, aluminum oxide and carbon monoxide. The modeling for a nominal dual Peacekeeper target launch showed that the peak hydrogen chloride standard would be exceeded out to a distance of approximately 625 meters beyond the Vandenberg AFB boundary (table 4.5.1-6). The 1-hour, 8-hour, and 24-hour hydrogen chloride standards would not be exceeded. Emission levels for both carbon monoxide and aluminum oxide would be within NAAQS and California AAQS. A nominal launch of a single Peacekeeper Target is anticipated to be within the NAAQS, California AAQS, and Air Force standards as fewer emissions would be released.

(1) Based upon NAAQS
(2) Based upon the maximum California AAQS level of PM-10 concentrations over a 24-hour period
(3) Based upon Air Force standards that measured and estimated launch emission exposure concentrations and durations in the event of normal and catastrophic launches

The *de minimis* thresholds are federal limits listed in 40 CFR 51.583(b)(1). In the event that 5 Peacekeeper Targets are launched in a year, the conservatively estimated annual emissions for oxides of nitrogen would total 18.3 metric tons (20.2 tons), below the 45.3-metric-ton (50-ton) limit. Carbon monoxide was calculated to be 48.8 metric tons (53.8 tons), also below the federal limit of 90.7 metric tons (100 tons).

If flight termination becomes necessary, the potential resulting fire would cause short-term impacts to air quality in the form of combustion byproducts and potentially hazardous fumes. Most or all of the solid propellant fuel would likely burn up before being extinguished. These combustion byproducts would be similar to those previously described for a nominal launch. Modeling using the OBODM was also performed to analyze emissions produced in the highly unlikely occurrence of an on-pad accident involving dual Peacekeeper Targets. As shown in table 4.5.1-6, the 1-hour and peak hydrogen chloride Air Force standards would be exceeded. The 8-hour and 24-hour hydrogen chloride standards were not exceeded. All other standards would continue to be within NAAQS and California AAQS. The consequences to regional air quality would be localized (within approximately 3.8 kilometers (2.4 miles) of Vandenberg AFB for the peak hydrogen chloride standard and 1.3 kilometers (0.8 miles) of Vandenberg AFB for the 1-hour hydrogen chloride standard) and would be of a short duration. The modeling included both day and nighttime meteorological data. Nighttime data typically depicts very calm wind conditions which results in higher emission concentrations. Due to the highly unlikely potential for a dual accident, the localized short term nature of the air quality exceedence, and
the conservative nature of the OBODM inputs, the impact to regional air quality is considered minor.

Potential health and safety impacts due to launch emissions are discussed under section 4.5.6, Health and Safety. Before each launch, the Rocket Exhaust Effluent Diffusion Model is used to locate toxic zones. A toxic risk-assessment-based recommendation to launch or not to launch is based on the results of the LATRA program that evaluates the risk to people, regardless of whether they are mission essential or non-mission essential. Among other criteria in determining whether to launch, the LATRA accounts for (1) whether people are sheltered or unsheltered; (2) whether they are healthy or sensitive individuals; and (3) the probability of a catastrophic launch failure.

**Determination of Non-Applicability**

Santa Barbara County is in non-attainment for the state standards for ozone and PM-10 and is currently in the process of being redesignated by the EPA as being in attainment for the federal ozone standard. The review of the Proposed Action as required by the General Conformity Rule resulted in a finding of presumed conformity. Total foreseeable direct and indirect emissions caused by the proposed action are less than the mandated *de minimis* thresholds as shown in appendix J.

**Post-Launch Activities**

Post-launch activities would include the removal of all mobile equipment and assets brought to Vandenberg AFB. The removal could result in small localized amounts of PM-10, which would be minimized further through dust suppression measures previously discussed.

**4.5.1.2.2 Sensors**

Current range radars (such as High Accuracy Instrument Radar, AN/TPQ-18, AN/FPS-16, AN/MPS, and TPS-X), sensors, fixed and mobile telemetry, and optics equipment would be utilized in Alternative 1 and would require no construction or modifications. Operation of existing range radars at Vandenberg AFB would be covered under existing permits.

**4.5.1.3 Alternative 2**

**4.5.1.3.1 Ground-Based Interceptors**

**Construction**

The modification of LF-21 and LF-23 to support GBI launches, and the modification of associated facilities to be used at Vandenberg AFB was analyzed in the Booster Verification EA and the Alternate Booster Vehicle EA and determined to cause no significant air quality impacts to the regional air. The proposed action would include the use of up to two GBI silos. LF-21 and LF-23 could be used with very minor modifications. LF-02, LF-03, LF-10, and LF-24 would require varying levels of modification. Modifications would include those described in section 2.3.2.1.2. Additional facilities listed in table 2.3.2-1 would also require modifications. All construction staging areas would be located on paved or previously disturbed graded areas. The GMD program would perform sampling and abatement for lead-based paint, asbestos, and PCBs as required before modification, using Vandenberg AFB-approved procedures. Facility
modifications and site preparation activities at the locations identified would have a localized, minimal impact on air quality.

For communication among the components at Vandenberg AFB, the proposed action would maximize use of available communications assets, to include cable. If communication cable is not available, new cable would be installed in new conduits. Cable routes would be designed to avoid environmental impacts and would be approved by 30 CES/CEV. Installation of cable would have a localized, minimal impact on air quality.

Operation

Pre-Launch Activities

Pre-launch activities associated with the GBIs would be similar to pre-launch activities for targets at Vandenberg AFB.

An accidental release of liquid fuel or liquid oxidizer from the EKV would be similar to that described for KLC in section 4.1.1.2.1. During nominal propellant tank installation, the propellants remain sealed inside their tanks. The likelihood of an accidental release of the liquid fuel or oxidizer would be low; however, if such an accident were to occur, it would most likely occur during missile assembly. Table 4.5.1-7 indicates the results of analysis using the U.S. Air Force Toxic Corridor Model computer model to determine distances at which IDLH health standard could be exceeded assuming all 7.5 liters (2 gallons) of fuel and 5.5 liters (1.5 gallons) of oxidizer were released to the atmosphere during an accident. The IDLH is the level of exposure (not time-weighted) above which it is thought a person would suffer life-threatening or irreversible health effects or other injuries that would impair them from escaping the hazardous environment. The IDLH level was the only level of concern as others are based on time weighted averages over prolonged exposures.

Actual hazard distances would depend on the propellant released, the amount released, meteorological conditions, and emergency response measures taken. However, the low likelihood of such an event and the implementation of approved emergency response plans would limit the impact of such a release.

Launch Activities

Alternative 2 launch activities include up to five launches (GBI and target combined) per year at Vandenberg AFB over the duration of the test program and would also comply with the rules listed in section 4.5.1.2.1. Table 4.5.1-8 lists propellant information for the proposed GBI configuration and table 4.5.1-9 gives emissions constituents for Stage 1 of the proposed GBI configuration. Emissions from rocket and missile launches are not considered stationary sources by the Santa Barbara County Air Pollution Control District.

As determined in the Booster Verification Test EA (U.S. Department of the Air Force, 1999) the configuration of the proposed GBI is similar to that of the Athena-2 (formerly the Lockheed Martin Launch Vehicle). However, the Athena-2 has a much larger solid rocket fuel capacity compared to that of the GBI. Air quality emission modeling in the Booster Verification Test EA (U.S. Department of the Air Force, 1999) concluded that a normal launch of an Athena-2 at Vandenberg AFB would not cause a significant impact to regional air quality; therefore, the much lower levels of the GBI exhaust would not be expected to cause a significant impact to air quality.

Dual GBI launches were analyzed using OBODM to determine exhaust emissions of aluminum oxide, hydrogen chloride, and carbon monoxide. Table 4.5.1-10 lists emission concentrations and standards. As shown on the table, all concentrations produced by dual launches of a GBI would remain within NAAQS, California AAQS, and U.S. Air Force standards. It is anticipated that a nominal single launch would also remain within NAAQS, California AAQS, and U.S. Air Force standards for aluminum oxide, hydrogen chloride, and carbon monoxide as fewer emissions would be released.

(1) Based upon NAAQS
(2) Based upon the maximum California AAQS level of PM-10 concentrations over a 24-hour period
(3) Based upon Air Force standards that measured and estimated launch emission exposure concentrations and durations in the event of normal and catastrophic launches

The \textit{de minimis} thresholds are federal limits listed in 40 CFR 51.583(b)(1) for non-attainment areas. In the event that 5 GBIs are launched in a year, the conservatively estimated annual emissions for oxides of nitrogen would total 31.8 tons, below the 50 ton \textit{de minimis} limit. Carbon monoxide was calculated to be 5.4 tons, also below the federal limit of 100 tons.

Modeling using the OBODM was also performed to analyze emissions produced in the highly unlikely occurrence of an on-pad accident involving dual GBIs. Results of the modeling show that both the 1-hour and peak hydrogen chloride U.S. Air Force standards would be exceeded (table 4.1.1-10). The 24-hour hydrogen chloride standard was not exceeded. The consequences to regional air quality would be localized (within approximately 2.5 kilometers [1.6 miles] of Vandenberg AFB for both the 1-hour and peak hydrogen chloride U.S. Air Force standards) and would be of short duration (less than 24 hours). The modeling included both day and nighttime meteorological data. Nighttime data typically depicts very calm wind conditions, which result in higher emission concentrations. Due to the highly unlikely potential for a dual accident, the localized short term nature of the air quality exceedence, and the conservative nature of the OBODM inputs, the impact to regional air quality is considered minor.

As described above in 4.5.1.2.1, potential health & safety impacts due to launch emissions are discussed under section 4.5.6, Health and Safety. Models are run before each launch to evaluate the risk to people.

\textit{Determination of Non-Applicability}

Santa Barbara County is in non-attainment for the state standards for ozone and PM-10 and is currently in the process of being redesignated by the EPA as being in attainment for the federal ozone standard. The review of the proposed action as required by the General Conformity Rule resulted in a finding of presumed conformity. Total foreseeable direct and indirect emissions caused by the proposed action are less than the mandated \textit{de minimis} thresholds as shown in appendix J.
Post-Launch Activities
Post-launch activities would include the removal of all mobile equipment and assets brought to Vandenberg AFB. The removal could result in small localized amounts of PM-10, which would be minimized further through dust suppression measures previously discussed.

4.5.1.3.2 Targets
Target construction and operation at Vandenberg AFB for Alternative 2 would be the same as described in section 4.5.1.2.1 for Alternative 1.

4.5.1.3.3 In-Flight Interceptor Communication System Data Terminal
Construction
An IDT site would be constructed for Alternative 2, requiring the disturbance of approximately 5.9 hectares (14.6 acres). Construction would last for approximately 7 months. The potential construction emissions are listed in Table 4.5.1-11.

<table>
<thead>
<tr>

<td>0.11 (0.13)</td>
</tr>
<tr>
<td>PM-10</td>
<td>4.8 (5.3)</td>
</tr>
</tbody>
</table>

As Vandenberg AFB is within a non-attainment area for the California AAQS 1-hour ozone standard, exhaust emissions of nitrogen oxides and hydrocarbons would be of concern. Construction emission levels would be below de minimis levels set by the federal government as analyzed in appendix J. Limits are set for carbon monoxide (90.7 metric tons [100 tons]), oxide of nitrogen (45.3 metric tons [50 tons]), volatile organic compounds (45.3 metric tons [50 tons]), oxides of sulfur (90.7 metric tons [100 tons]), and PM-10 (90.7 metric tons [100 tons]). Emissions would be monitored in accordance with Memorandum of Agreements between Vandenberg AFB and Santa Barbara County Air Pollution Control District. Therefore, impacts are not expected to be substantial.

Operation
Operation of the IDT at Vandenberg AFB would have little effect on regional air quality. Power would be provided by offsite commercial power sources; however, in the event of a loss of power a 275-kW diesel generator would be used. Along with the generator itself, there would be a 3,785-liter (1,000-gallon) AST for fuel. Table 4.5.1-12 lists the possible emissions associated with the use of this generator. The generator is assumed to be tested weekly during non-launch periods and used during power outages for approximately 200 hours a year.
### Table 4.5.1-12: Potential Generator Emissions for IDT Facilities at Vandenberg AFB

<table>
<thead>
<tr>
<th>Emissions</th>

<td>0.07 (0.08)</td>
<td>0.63 (0.70)</td>
<td>0.02 (0.03)</td>
</tr>
</tbody>
</table>

All generators, including the proposed 275-kW generator for the IDT, would be operated under appropriate permits and restrictions, which could possibly include New Source Review permitting, emission offsets, or emission control equipment.

#### 4.5.1.3.4 Sensors

Current range radars (such as High Accuracy Instrument Radar, AN/TPQ-18, AN/FPS-16, AN/MPS, and TPS-X), sensors, fixed and mobile telemetry, and optics equipment would be utilized in Alternative 2 and would require no construction or modifications.

#### 4.5.1.4 Alternative 3

Alternative 3 would require the use of pre-existing missile support facilities and range radars. Air quality impacts for these activities are similar to those described for Alternatives 1 and 2.

#### 4.5.1.5 Cumulative Impacts

Launches from Vandenberg AFB are limited to 30 annually (10 military launches and 20 space launches). The prior EAs that analyzed GMD activities at Vandenberg AFB (U.S. Army Space and Missile Defense Command, 2002a; U.S. Department of the Air Force, 1999) indicated no cumulative impact to air quality for up to six GBI launches annually. Based on preliminary planning information through fiscal year 2007, the Proposed Action of up to five launches (interceptor and target), in conjunction with current planned or anticipated launches, would not exceed the 30 annual launches from Vandenberg AFB.

Initial defensive operations capabilities being developed at Vandenberg AFB would not include missile launches. Backup generator emissions at four GBI LFs, and minor site preparation emissions would be regulated in accordance with MOAs between Vandenberg AFB and the Santa Barbara County Air Pollution Control District and would not result in cumulative impacts to air quality.

#### 4.5.1.6 Mitigation Measures

No air quality mitigation measures are proposed for the GMD ETR activities at Vandenberg AFB.

#### 4.5.2 BIOLOGICAL RESOURCES—VANDENBERG AIR FORCE BASE

The biological resources analytical approach involved evaluating the potential impacts of the Proposed Action and alternatives, such as construction, site preparation activities, use of existing and new sensors, and missile launches, on vegetation, wildlife, threatened and
endangered species, and sensitive habitat within the ROI. Impacts that could result from construction and other site preparation activities include disturbance and removal of vegetation and disturbance to wildlife from the accompanying noise and presence of personnel. Impacts could also result from launch-related activities such as noise, air emissions, debris impacts, and the use of radar equipment.

All transportation of equipment and materials such as fuels would be conducted in accordance with applicable federal (DOT) and state regulations. SOPs for spill prevention, containment, and control measures while transporting equipment and materials would preclude impacts to biological resources.

GMD ETR program personnel would remove all mobile equipment/assets brought to the installation at the conclusion of its testing activities. Transportation for removal of equipment would be the same as when it was brought into the installation. These activities would result in impacts similar to, but less than, those caused by site preparation. Specific restoration actions, if necessary, would be determined on a case-by-case basis.

4.5.2.1 No Action Alternative

If the GMD ETR is not established, Vandenberg AFB would still continue to be operated as a test area for space and missile operations. Other GMD-related activities would continue such as the GBI test flights addressed in the EA for Booster Verification Tests (U.S. Department of the Air Force, 1999) and the Alternate Booster Vehicle Verification Tests EA (U.S. Army Space and Missile Defense Command, 2002c) and single target launches. These activities are consistent with the ongoing mission of Vandenberg AFB and have been analyzed by the referenced EAs. No additional impacts to biological resources would occur as a result of the No Action Alternative.

4.5.2.2 Alternative 1

4.5.2.2.1 Targets

Target missiles are currently launched from LF-6 and LF-3 in support of the GMD program. Up to five target missiles per year could be launched from Vandenberg AFB to support the GMD ETR program over the 10-year performance period. Dual target missile launches could potentially occur.

Construction

Vegetation

Alternative 1 would require the use of existing LFs (LF-6 and LF-3) (figure 3.5.2-1), a Missile Assembly Building (Building 6816), and missile and maintenance storage facilities. No new construction would be needed to support target launches for this alternative. The minor site preparation activities would result in no ground disturbance, and thus there would be no impacts to vegetation.

Threatened and Endangered Plant Species. No adverse impacts are anticipated to the Gaviota tarplant and Lompoc yerba santa as a result of site preparation activities since no ground disturbance is anticipated.
Wildlife
Site preparation activities would implement procedures to minimize the potential for soil erosion if necessary and are not expected to adversely affect waterbodies, including Essential Fish Habitat. Site preparation activities would be limited in duration, and no direct physical auditory changes are anticipated.

California sea lions, northern elephant seals, northern fur seals, and other sensitive marine mammals in adjacent offshore areas would normally be at least 296 meters (970 feet) from the closest launch site (LF-6) and are not expected to be affected by site preparation noise.

Threatened and Endangered Wildlife Species. Site preparation activities would not occur in areas that could result in impacts to water bodies that could potentially contain the tidewater goby, unarmored threespine stickleback, or California red-legged frog.

The California brown pelican and western snowy plover preferentially forage and roost along the coast approximately 296 meters (970 feet) away and are unlikely to be affected by site preparation noise. Site preparation activities are also not anticipated to result in impacts to the southern sea otter or other sensitive marine mammals in adjacent offshore areas due to the distance from the proposed GMD-related facilities to the shoreline (approximately 296 meters [970 feet]).

Environmentally Sensitive Habitat
The coastal dune systems are outside the area that could potentially be disturbed during site preparation activities at LF-6 or LF-3. Site preparation activities are not anticipated to directly or indirectly impact the nearest wetlands, which are approximately 1.6 kilometers (1 mile) northwest of Building 1819.

Operation
Vandenberg AFB typically supports approximately five Minuteman or Peacekeeper launches per year from northern launch sites on base. Based on previous environmental studies and a Letter of Authorization with the National Marine Fisheries Service, up to 10 Minuteman and Peacekeeper launches per year could occur from northern Vandenberg AFB launch sites. GMD target missiles would be included in this number. Up to five GMD target launches would occur per year from north Vandenberg AFB. Dual target missile launches could potentially occur. Dual launches could result in a slightly larger affected area and longer duration of disturbance to wildlife. Impacts would in some cases be slightly greater than, but similar to, those analyzed below for single launches.

Vegetation
Normal launch activities are not expected to impact vegetation. Launch exhaust products would include hydrogen chloride, aluminum oxide, carbon monoxide, nitrogen dioxide, carbon dioxide, water, and chlorine. Nominal launch activities during dry conditions could result in the deposition of very small amounts of aluminum oxide from missile exhaust. Most of the aluminum oxide would be suspended in air and dispersed over extremely large areas; the amount deposited in surface waters would have little effect. Under natural conditions, the chemical is not a source of toxic aluminum; the EPA has determined that non-fibrous aluminum oxide, as found in solid rocket motor exhaust, is nontoxic (U.S. Department of the Air Force,
Analysis of launch-related deposition of aluminum oxide has not shown it to be harmful to vegetation (Federal Aviation Administration, 1996).

The greatest potential for impacts to vegetation comes from hydrogen chloride deposition. Direct effects could include discoloration, foliage loss, and changes in species composition. Rain within 2 hours of launch could cause hydrogen chloride to be deposited in small quantities. This chemical, when emitted during solid propellant missile launches for very large flight vehicles (such as the Space Shuttle), is known to injure plant leaves and affect wildlife. However, the potential impact on vegetation and wildlife from the proposed launches of the smaller target missiles is expected to be slight. The hydrogen chloride would cause a change in marine or fresh surface water pH for only a short duration; any alteration of the water’s pH would be almost imperceptible. (U.S. Department of the Air Force, 1997b)

Vandenberg AFB has a wildland fuels management plan, prepared by the U.S. Forest Service, containing measures to help prevent large wildfires (such as prescribed burning activities, which lower the age class of area vegetation). Moreover, emergency fire-fighting personnel are on standby status for all launch activities as a protective measure.

**Threatened and Endangered Plant Species.** No adverse impacts are anticipated to the Gaviota tarplant and Lompoc yerba santa as a result of nominal launch activities since these plants have not been identified at the proposed target launch sites.

**Wildlife**

**Emissions.** The small quantities of hydrogen chloride that could potentially be deposited are not expected to injure or affect wildlife. The hydrogen chloride would cause a change in surface water pH for only a short duration, and any alteration of the water’s pH would be almost imperceptible. The EPA has determined that non-fibrous aluminum oxide from solid rocket exhaust is non-toxic (Vandenberg Air Force Base, 1999).

**Threatened and Endangered Wildlife Species.** As mentioned above, hydrogen chloride and aluminum oxide deposition is not anticipated to adversely affect wildlife, including threatened or endangered wildlife species.

**Noise.** The primary potential for impacts to wildlife would be from the noise created during the proposed missile launches. Wildlife in general is known to exhibit a startle response when exposed to short-term noise impacts. Waterfowl would quickly resume feeding and other normal behavior patterns after a launch is completed. Studies indicate that birds usually show signs of disturbance, such as fluttering of wings, when the noise occurs, but quickly return to normal behavior after the event (U.S. Department of the Air Force, 1997b). Disturbance to wildlife from the launches would be brief and is not expected to have a lasting impact nor a measurable negative effect on migratory bird populations.

Pacific harbor seals, the main pinniped species using north Vandenberg AFB, would normally be at least 2.0 kilometers (1.2 miles) from the launch site. Other pinnipeds such as California sea lions and northern elephant seals may haul-out temporarily on beaches several kilometers (miles) from the launch facility. Noise from prior launches has not appeared to affect pinniped use of the coastal areas on Vandenberg AFB. Pinniped monitoring has been performed for
launches of larger missiles on north Vandenberg AFB such as the Peacekeeper and Delta II. The effect to harbor seals, which were most susceptible to disturbance, has been a negligible short-term (5- to 30-minute) abandonment of a haul-out area at Spur Road and Purisima Point. No pinniped mother-pup separations have been noted at the harbor seal haul-out sites closest to the launch site. Recent surveys discovered a new harbor seal haul-out site on north Vandenberg AFB that is regularly used by up to three harbor seal mothers and their pups. The U.S. Air Force, 30 SW, Vandenberg AFB began monitoring harbor seals at this site for Minuteman and Peacekeeper launches (launch reports in preparation) that occurred during the harbor seal pupping season (March–June) in accordance with the 5-year programmatic permit and Letter of Authorization issued by National Marine Fisheries Service to the 30 SW.

Noise monitoring would be performed during the initial launch of GMD target missile and harbor seal monitoring would be conducted during the pupping season in accordance with Vandenberg AFB guidelines. The target launches would be included in the number of intercontinental ballistic missile currently allowed under Vandenberg AFB’s 5-year programmatic permit and Letter of Authorization. If the annual launch rates from Vandenberg AFB increase above the levels currently projected and covered under the National Marine Fisheries Service authorization, the Letter of Authorization would be amended accordingly with appropriate analysis of impacts to marine mammals.

Threatened and Endangered Wildlife Species. Prior agency consultations have provided both for regulatory agency assessments of missile programs on Vandenberg AFB and identified monitoring/minimization measures to ensure there are no significant impacts. These consultations have been addressed in several documents: USFWS Biological Opinion for the Theater Ballistic Missile Targets program, May 1998; the Threatened/Endangered Species Monitoring Plan for the Theater Ballistic Missile Targets Program prepared in compliance with the Biological Opinion, September 1999; and the Programmatic Marine Mammal Incidental Harassment Authorization for Space and Missile Launches on Vandenberg AFB, May 2000. (Vandenberg Air Force Base, 2002a)

The California brown pelican and western snowy plover preferentially forage and roost along the coast approximately 296 meters (970 feet) away from the proposed launch area. The California least tern has only nested at Purisima Point (over 11 kilometers [7 miles] from the nearest proposed LF) in recent years and has never been recorded nested north of San Antonio Creek (Vandenberg Air Force Base, 2003). No effects to sensitive bird species have been identified from prior launches in the area. Proposed launch activities are unlikely to adversely affect the long-term wellbeing, reproduction rates, or survival of these listed birds. The level of noise during launch and flight is also expected to be relatively short in duration. Noise monitoring would be performed in accordance with Vandenberg AFB guidelines.

Southern sea otters in adjacent offshore areas would also be at least 296 meters (970 feet) from the launch site. Noise from prior launches has not appeared to affect sea otter use of the coastal areas on Vandenberg AFB. Noise from launches of the larger Delta II missile has not affected use of coastal areas by sea otters with dependent pups. Disturbance as a result of visual stimulus is unlikely because the target missile would be at an altitude of 407 meters (1,335 feet) as it arches past the coastline. The intermittent launches planned for the GMD ETR test flights (up to five target missile flights per year over a 10-year period) are not expected to substantially impact the southern sea otter. (U.S. Department of the Air Force, 1997b; 1999)
Debris. Nominal launch activities are not expected to adversely impact Essential Fish Habitat. Although spent boosters and intercept debris could affect any species close to the surface, the number of individuals injured or killed would not likely affect overall species’ populations. The majority of propellant would be expended before booster drop and impact, and thus only trace amounts of propellant would be left, which would minimize the potential for toxic effects. (U.S. Department of the Air Force, 2001)

In the unlikely event of a launch mishap, scattered pieces of burning propellant could enter coastal water and potentially affect Essential Fish Habitat and pinnipeds hauled out along the adjacent coastline. Concentrations of toxic materials would be highest in this shallow water and have a greater chance of being ingested by feeding animals. However, the potential for a launch mishap is relatively slight, and in most cases the errant missile would be moving at a rapid rate such that pieces of propellant and other toxic debris would likely strike the water further downrange. Unburned solid fuel is hard and rubber-like, and any ammonium perchlorate would dissolve slowly out of the rubber-like binder, producing ammonia and chlorine that would disperse into the marine waters. Were hazardous materials to leach out of the intercept debris, the great volume of water in the ocean would dilute the contaminant to acceptable levels. The solid fuel’s aluminum oxide is insoluble; in addition, as the fuel slowly dissolves, its outer layers become spongy, further retarding dissolution. Thus no toxic levels of ammonia, chlorine, or aluminum would be expected. A recent study conducted for the U.S. Air Force (Lang, et al, 2000) measured the amount of perchlorate lost from solid propellant samples immersed in fresh and salt water. From the measurement of the concentration of the perchlorate ion in solution, the mass fraction loss of the propellant sample due to perchlorate leaching was calculated. The results are presented in the KLC Water Resources section, table 4.1.14-2. As shown in the table, it would take approximately 270 days for 90 percent of the perchlorate to leach out of solid propellant that lands in the ocean (at 29°C). The perchlorate would be expected to be diluted as it mixes with the surrounding water. The debris would also be widely scattered, which would reduce the possibility of ingestion. As mentioned above, the number of individuals injured or killed would not likely affect overall species’ populations. (U.S. Department of the Air Force, 2001)

Potential exists to disturb biological resources during debris recovery activities; however, recovery efforts would be coordinated with applicable range representatives and agencies to develop appropriate mitigation measures to avoid impact to sensitive resources and to restore natural areas as necessary following debris recovery efforts. Negligible adverse effects to biological resources would be expected during debris recovery activities.

Fire from an early flight termination could impact terrestrial wildlife near the launch site. However, emergency fire-fighting personnel are on stand-by status for all launch activities as a protective measure.

In the unlikely event of an accidental release of stored liquid propellant, Vandenberg AFB’s Hazardous Materials Emergency Response Plan and Spill Control and Countermeasures Plan would be implemented in order to prevent impacts to biological resources in the vicinity. All applicable U.S. Air Force, DOT, and U.S. Army safety regulations and OSHA requirements would be followed, which would minimize the potential for accidental spills, as well as provide the means for mitigating or minimizing effects to wildlife if an accident were to occur. With the plans mentioned above in place, no impacts to wildlife are expected as a result of accidental release of liquid propellant.
**Threatened and Endangered Wildlife Species.** Impacts to threatened and endangered species resulting from proposed GMD ETR activities would be similar to those addressed above for wildlife. Debris from nominal launches is not expected to impact water bodies that could potentially contain the tidewater goby, unarmored threespine stickleback, or California red-legged frog. Since the westerly launch trajectory used for most missile launches would carry the missile over snowy plover habitat, fire and debris from an anomaly could potentially impact snowy plovers. However, as stated above, emergency fire-fighting personnel are on stand-by status for all launch activities as a protective measure. Any required recovery activities would follow Vandenberg AFB SOPs with negligible adverse effects expected to the snowy plovers and their habitat. The reproductive success of the snowy plover does not appear to have been affected by prior launches.

Debris impact and booster drops in the BOA off the coast are not expected to adversely affect marine mammal species protected by the Marine Mammal Protection Act of 1972. An early flight termination or mishap could result in debris impact along the flight corridor. Early flight termination could result in widely scattered debris, but the probability of this debris hitting wildlife is remote since sensitive marine species in the ocean are widely scattered and occupy relatively small surface areas, and the probability of debris striking a threatened or endangered species is considered remote, $1 \times 10^{-6}$ or less than 1 in 1 million.

**Environmentally Sensitive Habitat**

No adverse impacts as a result of the GMD ETR activities are anticipated to occur within the current Channel Islands National Marine Sanctuary located off the coast south of Vandenberg AFB. Additional consultation would be performed with the National Oceanographic and Atmospheric Administration following their decision on the sanctuary boundary expansion.

**4.5.2.2 Sensors**

Existing range sensors at Vandenberg AFB include several range radars (AN/TPQ-18, AN/FPS-16, High Accuracy Instrumentation Radar, AN/MPS-39, TPS-X) as well as fixed and mobile telemetry and optics equipment. Launch control would be located in existing launch control facilities. No additional impacts to biological resources would result from these existing sensors in support of the GMD ETR activities.

**4.5.2.3 Alternative 2**

Alternative 2 would be similar to Alternative 1 with the exception that GBI launches would be from Vandenberg AFB and RTS instead of KLC and RTS. The GBI launch would require construction of an IDT and modifications of existing support facilities at Vandenberg AFB. The other components described in Alternative 1 would remain the same.

**4.5.2.3.1 Ground-Based Interceptors**

Under Alternative 2, Vandenberg AFB would continue to be a launch site for GMD target missiles and would support dual GBI launches. The following activities would continue at Vandenberg AFB: dual launch of target missiles, dual launch of GBI missiles, use of the TPS-X radar, and use of existing range instrumentation.
Construction

Vegetation
Facilities located on north Vandenberg AFB that may be required for the GBI tests are listed in table 2.3.2-1 and shown on figures 2.3.2-1 and 3.5.2-1. Minor internal modification and construction (potential expansion of parking areas) could be required as part of proposed site preparation activities for, and thus there would be little to no ground disturbance and resultant impact to vegetation in or around applicable LFs, as well as required support buildings. Some facilities have been used to support GBI booster verification tests and, as such, would require only minor interior modifications to support continued GMD testing, and therefore no vegetation impacts are anticipated.

For communication among the components on the same installation, the ETR would maximize use of available communications assets to include cable. Cables would be installed in existing conduits, where available. If existing conduits are not available, the cable(s) would be installed in new conduits that would be placed in routes along existing roads designed to avoid environmental impacts and approved by 30 CES/CEV. Once communication line routes are selected, biological surveys would be conducted as required. Trenching for the new communications cable/conduit would have a maximum depth of 0.91 meter (3 feet). Slant/directional drilling is also being proposed as a means of minimizing impacts to the environment if required.

Threatened and Endangered Vegetation. No adverse impacts are anticipated to the Gaviota tarplant and Lompoc yerba santa as a result of site preparation activities since these plants have not been identified in the vicinity of proposed launch facilities.

Wildlife
Site preparation activities, which would include fiber optic cable installation, would implement procedures to minimize the potential for soil erosion, such as the use of slant/directional drilling, and are not expected to adversely affect waterbodies, including Essential Fish Habitat.

Site preparation activities would be limited in duration, and no direct physical auditory changes are anticipated. Typically the noise at 15 meters (50 feet) from a construction site does not exceed an equivalent sound level of 90 dBA. Most of the site preparation noise and human activity would be caused by truck traffic to and from the launch site and the potential short-term use of heavy machinery. Site preparation may disturb wildlife in the immediate area. The effects of noise on wildlife vary from serious to no effect in different species and situations. Behavioral responses to noise also vary from startling to retreat from favorable habitat, due partly to the fact that wildlife can be very sensitive to sounds in some situations and very insensitive to the same sounds in other situations (Larkin, 1996).

Disturbance would be restricted mainly to areas within 15 meters (50 feet) from the construction site. The increased presence of personnel would tend to cause birds and other mobile species of wildlife to temporarily evacuate areas subject to the highest level of noise. Additional ruderal vegetation is nearby for displaced wildlife.
California sea lions, northern elephant seals, northern fur seals, and other sensitive marine mammals in adjacent offshore areas would normally be at least 731.5 meters (2,400 feet) from the launch site and are not expected to be affected by site preparation noise.

**Threatened and Endangered Wildlife.** Site preparation activities would not occur in areas that could result in impacts to water bodies that could potentially contain the tidewater goby, unarmored threespine stickleback, or California red-legged frog.

The California least tern, California brown pelican, and western snowy plover preferentially forage and roost along the coast approximately 731.5 meters (2,400 feet) or farther away from the proposed launch area and are unlikely to be affected by site preparation noise.

Site preparation activities are also not anticipated to result in impacts to the southern sea otter or other sensitive marine mammals in adjacent offshore areas due to the distance from the launch sites (approximately 731.5 meters [2,400 feet] or farther).

**Environmentally Sensitive Habitat**

The coastal dune systems are outside the area that could potentially be disturbed during site preparation activities at the LFs. Wetlands would be avoided to the maximum extent practicable. The use alternative methods of drilling for installation of required fiber optic cable could minimize the potential for impacts to wetlands or other sensitive habitat.

**Operation**

Dual GBI launches could potentially occur. Dual launches could result in a slightly larger affected area and longer duration of disturbance to wildlife. Impacts would in some cases be slightly greater than, but similar to, those analyzed below for single launches.

**Vegetation**

The majority of the blast residue would be contained within the silo, minimizing the potential for impacts on vegetation. All applicable U.S. Air Force, DOT, and U.S. Army safety regulations and OSHA requirements would be followed. Compliance with these regulations would minimize the potential for accidental spills, as well as provide the means for mitigating or minimizing effects to vegetation if an accident were to occur.

Nominal launch activities during dry conditions could result in the deposition of very small amounts of aluminum oxide from missile exhaust. Most of the aluminum oxide would be suspended in air and dispersed over extremely large areas; the amount deposited in surface waters would have little effect. Under natural conditions, the chemical is not a source of toxic aluminum; the EPA has determined that nonfibrous aluminum oxide, as found in solid rocket motor exhaust, is nontoxic (U.S. Department of the Air Force, 1997b).

Rain within 2 hours of launch could cause hydrogen chloride to be deposited in small quantities. This chemical, when emitted during solid propellant missile launches for very large flight vehicles (such as the Space Shuttle), is known to injure plant leaves and affect wildlife. However, the potential impact on vegetation and wildlife from the proposed launch of the smaller GBI is expected to be slight. The hydrogen chloride would cause a change in surface
water pH for only a short duration; any alteration of the water’s pH would be almost imperceptible. (U.S. Department of the Air Force, 1997b)

Vandenberg AFB has a wildland fuels management plan, prepared by the U.S. Forest Service, containing measures to help prevent large wildfires (such as prescribed burning activities which lower the age class of area vegetation). Moreover, emergency fire-fighting personnel are on stand-by status for all launch activities as a protective measure.

**Threatened and Endangered Vegetation.** No adverse impacts are anticipated to the Gaviota tarplant and Lompoc yerba santa as a result of nominal launch activities since these plants have not been identified at the proposed launch facilities.

**Wildlife**

**Emissions.** The small quantities of hydrogen chloride that could potentially be deposited are not expected to injure or affect wildlife. The hydrogen chloride would cause a change in pH of only short duration, and any alteration of the water’s pH would be almost imperceptible. The EPA has determined that non-fibrous aluminum oxide from solid rocket exhaust is nontoxic (Vandenberg Air Force Base, 1999).

**Threatened and Endangered Wildlife.** As mentioned above, hydrogen chloride and aluminum oxide deposition is not anticipated to adversely affect wildlife, including threatened or endangered wildlife species.

**Noise.** The primary potential for impacts to wildlife would be from the noise created during the proposed missile launches. Noise from Minuteman launches ranges from 98 dBA approximately 4.2 kilometers (2.6 miles) from the launch site to 80 dBA approximately 13 kilometers (8 miles) from the launch site. The level of noise for the GBI missile during launch and flight is expected to be less and relatively short in duration. At approximately the same distance from the LF, the previous booster vehicle-2 launch (GBI vehicle) was 6 dB less than the Minuteman III launch and 17 dB less than Peacekeeper launches.

Pacific harbor seals, the main pinniped species using north Vandenberg AFB, would normally be at least 2.0 kilometers (1.2 miles) from the launch site. Other pinnipeds such as California sea lions and northern elephant seals may haul-out temporarily on beaches several kilometers (miles) from the launch facility. Noise from prior launches has not appeared to affect pinniped use of the coastal areas on Vandenberg AFB. Pinniped monitoring has been performed for launches of larger missiles on north Vandenberg AFB such as the Peacekeeper and Delta II. The effect to harbor seals, which were most susceptible to disturbance, has been a negligible short-term (5- to 30-minute) abandonment of a haul-out area at Spur Road and Purisima Point. No pinniped mother-pup separations have been noted at the harbor seal haul-out sites closest to the launch site. Recent surveys discovered a new harbor seal haul-out site on north Vandenberg AFB that is regularly used by up to three harbor seal mothers and their pups. The U.S. Air Force, 30 SW, Vandenberg AFB began monitoring harbor seals at this site for Minuteman and Peacekeeper launches (launch reports in preparation) that occurred during the harbor seal pupping season (March-June) in accordance with the 5-year programmatic permit and letter of authorization issued by National Marine Fisheries Service to the 30 SW.
Noise monitoring would be performed during the initial launch of a GBI and harbor seal monitoring would be conducted during the pupping season in accordance with Vandenberg AFB guidelines. The target launches would be included in the number of intercontinental ballistic missile currently allowed under Vandenberg AFB’s 5-year programmatic permit and Letter of Authorization. If the annual launch rates from Vandenberg AFB increase above the levels currently projected and covered under the National Marine Fisheries Service authorization, the Letter of Authorization would be amended accordingly with appropriate analysis of impacts to marine mammals.

The disturbance to pinnipeds as a result of visual stimulus is unlikely due to the approximate altitude of 1,250 meters (4,100 feet) a GBI could reach as it approaches the coastline. The intermittent launches planned for the GBI test flights (up to five per year) are not expected to substantially impact marine species. (U.S. Department of the Air Force, 1999)

Wildlife in general is known to exhibit a startle response when exposed to short-term noise impacts. Studies (U.S. Department of the Air Force, 1997b) indicate that birds usually show signs of disturbance, such as the flutering of wings, when the noise occurs but quickly return to normal behavior after the event. Disturbance to wildlife from the launches would be brief and is not expected to have a lasting impact nor a measurable negative effect on migratory bird populations. Waterfowl would quickly resume feeding and other normal behavior patterns after a launch is completed.

Threatened and Endangered Wildlife. The California brown pelican and western snowy plover preferentially forage and roost along the coast approximately 1,250 meters (4,100 feet) away from the proposed launch area. Noise levels 4.2 kilometers (2.6 miles) from the launch site during previous Minuteman missile launches were 98 dBA. No effects to sensitive bird species have been identified. The GBI is a smaller vehicle with less propellant than a Minuteman, and lower noise levels are anticipated. Proposed launch activities are unlikely to adversely affect the long-term well-being, reproduction rates, or survival of these listed birds. The level of noise for the GBI during launch and flight is also expected to be relatively short in duration. Noise monitoring would be performed for the first launch.

Southern sea otters in adjacent offshore areas would also be at least 1,250 meters (4,100 feet) from the launch site. Noise from prior launches has not appeared to affect sea otter use of the coastal areas on Vandenberg AFB. Noise from launches of the larger Delta II missile has not affected use of coastal areas by sea otters with dependent pups. Disturbance as a result of visual stimulus is unlikely because the GBI would be at an altitude of 1,250 meters (4,100 feet) as it approaches the coastline. The intermittent launches planned for the GBI test flights (up to five flights per year) are not expected to substantially impact the southern sea otter. (U.S. Department of the Air Force, 1997b; 1999)

Debris. Nominal launch activities are not expected to adversely impact Essential Fish Habitat. Although spent boosters and intercept debris could affect any species close to the surface, the number of individuals injured or killed would not likely affect overall species’ populations. The majority of propellant would be expended before booster drop and impact, and thus only trace amounts of propellant would be left, which would minimize the potential for toxic effects. (U.S. Department of the Air Force, 2001)
In the unlikely event of a launch mishap, scattered pieces of burning propellant could enter coastal water and potentially affect pinnipeds hauled out along the adjacent coastline and Essential Fish Habitat. Concentrations of toxic materials would be highest in this shallow water and have a greater chance of being ingested by feeding animals. However, the potential for a launch mishap is relatively slight, and in most cases the errant missile would be moving at a rapid rate such that pieces of propellant and other toxic debris would strike the water further downrange. The debris would also be widely scattered, which would reduce the possibility of ingestion. As mentioned above, the number of individuals injured or killed would not likely affect overall species’ populations. (U.S. Department of the Air Force, 2001)

Debris impact and booster drops in the BOA off the coast are not expected to adversely affect marine mammal species protected by the Marine Mammal Protection Act of 1972. An early flight termination or mishap could result in debris impact along the flight corridor. Early flight termination could result in widely scattered debris, but the probability of this debris hitting wildlife is remote.

Fire from an early flight termination could impact terrestrial wildlife near the launch site. However, emergency fire-fighting personnel are on standby status for all launch activities as a protective measure.

In the unlikely event of an accidental release of stored liquid propellant, Vandenberg AFB’s Hazardous Materials Emergency Response Plan and Spill Control and Countermeasures Plan would be implemented in order to prevent impacts to biological resources in the vicinity. All applicable U.S. Air Force, DOT, and U.S. Army safety regulations and OSHA requirements would be followed, which would minimize the potential for accidental spills, as well as provide the means for mitigating or minimizing effects to wildlife if an accident were to occur. With the above plans in place, no impacts to wildlife are expected as a result of accidental release of liquid propellant.

*Threatened and Endangered Wildlife.* Debris from nominal launches is not expected to impact water bodies that could potentially contain the tidewater goby, unarmored threespine stickleback, or California red-legged frog.

As discussed above, sensitive marine species in the ocean are widely scattered and occupy relatively small surface areas, and the probability of debris striking a threatened or endangered species is considered remote.

*Environmentally Sensitive Habitat*

No adverse impacts to the coastal dune systems are anticipated as a result of launch activities. Personnel would be instructed to avoid bird nesting and roosting locations and pinniped haul-out areas. Nominal launch activities are not anticipated to impact the wetlands approximately 1.6 kilometers (1 mile) northwest of Building 1819. An early flight termination or mishap would result in widely scattered debris, which could potentially impact the wetlands. Debris would be recovered and removed if practicable.

No adverse impacts as a result of the GMD ETR activities are anticipated to occur within the current Channel Islands National Marine Sanctuary located off the coast south of Vandenberg.
AFB. Additional consultation would be performed with the National Oceanographic and Atmospheric Administration following their decision on the sanctuary boundary expansion.

4.5.2.3.2 In-Flight Interceptor Communication System Data Terminal Construction

Once an IDT site is selected, biological surveys would be conducted as required.

Vegetation

The IDT (figure 2.3.2-1) would require disturbance of approximately 5.9 hectares (14.6 acres), including a perimeter road, with a fenced area of approximately 3.2 hectares (8 acres). The minimal requirements include a concrete base for the COMSATCOM, an all-weather road to the site, and a prepared surface within the fence around the site at least 4.6 meters (15 feet) wide. This loss of vegetation would represent only a small portion of the total vegetation available within Vandenberg AFB boundaries.

Threatened and Endangered Plant Species. No federally proposed or listed candidate, threatened, or endangered plant species would be impacted by installation of the IDT.

Wildlife

Impacts from ground disturbance and equipment noise could include loss of habitat, displacement of wildlife, increased stress to wildlife, and disruption of daily or seasonal behavior. However, new construction would occur in previously disturbed areas to the maximum extent practicable. Additional habitat for species that could potentially be displaced is located adjacent to the areas proposed for disturbance. Site preparation activities would not result in impacts to Essential Fish Habitat since no water bodies would be affected.

Noise rather than the sight of machines appears to cause more disturbance to wildlife. The effects of noise on wildlife vary from serious to no effect in different species and situations. Behavioral responses to noise also vary from startling to retreat from favorable habitat (Larkin, 1996). As mentioned above, a short-term maximum noise exposure of 92 dB, which level is equivalent to being 1 meter (3 feet) from a power lawnmower, was suggested as a significant cut-off for impacts in a noise monitoring study for the HEDI I missile (U.S. Army Strategic Defense Command, 1990; 1989). This noise level is similar to the range of 80 to 90 dBA defined as known to disturb waterfowl and wildlife.

Typical noise levels at 15 meters (50 feet) from construction equipment range from 70 to 98 dBA. Wildlife is known to exhibit a startling response when exposed to short-term noise impacts. The combination of increased noise levels and human activity would likely displace some small mammals and birds that forage, feed, nest, or have dens within this 15-meter (50-foot) radius. However, sufficient foraging and feeding habitat occurs in adjacent areas. Studies (U.S. Department of the Air Force, 1997) indicate that birds usually show signs of disturbance, such as fluttering of wings, when a noise event occurs, but quickly return to normal behavior after the event. Although construction activities could cause flushing (birds suddenly flying up), this is a common reaction to sudden natural sounds that only slightly increases the energy expenditure of individual birds. Some wildlife may leave the area permanently, while others may likely become accustomed to the increased noise and human presence.
Locations proposed for IDT use are inland and site preparation would not impact Essential Fish Habitat; wildlife associated with the coast, such as hauled out pinnipeds; or marine mammals offshore. Site preparation activities would be limited in duration. Construction is therefore not expected to have a long-term significant adverse effect on wildlife.

**Threatened and Endangered Wildlife Species.** Disturbance from site preparation activities would be restricted mainly to areas within 15 meters (50 feet) from the construction site. Listed wildlife species such as the California brown pelican and southern sea otters would not be affected by site preparation noise since they are found along the coast or offshore. No waterbodies that support listed species would be affected by site preparation activities.

*Environmentally Sensitive Habitat*

No wetlands or other sensitive habitat would be disturbed during construction and installation of the IDT.

**Operation**

During normal operations, the IDT would not transmit except for a few minutes during annual testing of the equipment. Given the short duration of transmission, no adverse impacts to biological resources are anticipated. Most operational impacts to wildlife from the IDT would come from security lighting and noise from electrical generators required for the site. The lighting and noise could encourage species less tolerant of these disturbances to avoid the area. Generator noise could range from 80 to 85 dBA at up to 105 meters (344 feet). These noise levels would only occur a couple of hours a week during maintenance activities required for backup generators or continuously if no commercial power is available.

**4.5.2.3.3 Targets**

Impacts of site preparation and launch activities in support of target launches from Vandenberg AFB would be the same as those addressed in Alternative 1.

**4.5.2.4 Alternative 3**

Alternative 3 would consist of a combination of Alternative 1 and Alternative 2 with similar or the same potential for impacts to biological resources.

**4.5.2.5 Cumulative Impacts**

Prior EAs that analyzed GMD activities at Vandenberg AFB (U.S. Army Space and Missile Defense Command, 2002a; U.S. Department of the Air Force, 1999) indicated no cumulative impact to biological resources for up to six GBI launches annually. The proposed GMD launches would be included in the number of intercontinental ballistic missile currently allowed under Vandenberg AFB’s 5-year programmatic permit and Letter of Authorization. If the annual launch rates from Vandenberg AFB increase above the levels currently projected and covered under the National Marine Fisheries Service authorization, the Letter of Authorization would be amended accordingly with appropriate analysis of impacts to marine mammals. Missile launches are short-term, discrete events, thus allowing time between launches for emission products to be dispersed and minimizing the potential for cumulative impacts to vegetation and wildlife. Launch activities would also be performed at different times and locations. Debris from
the Proposed Action and other launch operations on Vandenberg would impact different areas of the Pacific Ocean. Therefore no cumulative impacts to biological resources are anticipated from the proposed missile launches when combined with other current and planned activities on Vandenberg AFB.

Initial defensive operations capabilities being developed at Vandenberg AFB would not include missile launches. However, operations would include backup generators at four GBI LFs, and minor site preparation activities. The operation of backup generators at each LF would be similar to those described above for the IDT, and would result in minor cumulative impacts.

No cumulative impacts to biological resources are expected as a result of fuel and oxidizer transport operations. Accidental releases or spills of liquid or gaseous materials would be contained or dispersed before reaching sensitive vegetation or wildlife. The amount of gaseous materials dispersed during launch is not expected to result in an increased potential for cumulative impact to marine species when combined with the missile launches currently planned from Vandenberg AFB.

### 4.5.2.6 Mitigation Measures

No biological resources mitigation measures are proposed for GMD ETR activities at Vandenberg AFB since noise monitoring during the initial launch of a GBI and harbor seal monitoring during the pupping season would be performed in accordance with current Vandenberg AFB SOPs.

### 4.5.3 CULTURAL RESOURCES—VANDENBERG AIR FORCE BASE

#### 4.5.3.1 No Action Alternative

Under the No Action Alternative, GMD ETR activities would not be established and Vandenberg AFB would be operated as a test area for space and missile operations. Other GMD activities would continue, such as the GBI test flights for Booster Verification tests. No additional impacts to cultural resources would occur as a result of the No Action Alternative.

#### 4.5.3.2 Alternative 1

##### 4.5.3.2.1 Target

**Construction**

Possible minor modifications may be required for both LF-6 and LF-3. Both of these are eligible for listing on the National Register of Historic Places. Prior to the reuse of these facilities, consultation would occur with the State Historic Preservation Officer to ensure their protection or appropriate mitigation to preserve information concerning the sites.

**Operation**

Proposed target operations for Alternative 1 at Vandenberg AFB would include single and dual launches of target missiles.
Flight Activities

Target launch activities would be similar to interceptor launches. Potential effects could result from debris striking the ground where surface or subsurface archaeological deposits or other cultural resources are located resulting in soil contamination, fire, and/or resource damage, which would all require a reparation effort. These efforts would be coordinated with applicable range representatives and agencies to develop appropriate mitigation measures to avoid impact to sensitive resources and to restore natural areas as necessary. Debris falling offshore would pose no threat to Vandenberg AFB’s cultural resources.

Lastly, potentially adverse effects to area historic and prehistoric resources could also occur as a result of the unauthorized collection of artifacts by flight preparation personnel. Personnel would receive a brief orientation involving a definition of cultural resources and protective federal regulations.

Post-Flight Activities

If required, debris recovery on land may involve the use of helicopters and off-road vehicles. Recovery of missile and missile components after unsuccessful launches would be conducted in accordance with Vandenberg AFB procedures. If the potential exists to disturb cultural resources during debris recovery activities, recovery efforts would be coordinated with Vandenberg AFB personnel to avoid impact to sensitive resources and to restore natural areas as necessary following debris recovery efforts.

4.5.3.2 Sensors

Operation

Existing range sensors at Vandenberg AFB include several range radars (AN/TPQ-18, AN/FPS-16, High Accuracy Instrumentation Radar, AN/MPS-39, TPS-X) as well as fixed and mobile telemetry and optics equipment. Launch control would be located in existing launch control facilities. No additional impacts to cultural resources would result from these existing sensors in support of the GMD ETR activities.

4.5.3.3 Alternative 2

4.5.3.3.1 Ground-Based Interceptors

Construction

Construction would include minor modifications to existing facilities. As project details are further delineated, coordination would occur with the Environmental Planning Section and the Cultural Resources Section at Vandenberg AFB to further ensure that cultural resources would be protected. The GMD Project Office would be responsible for implementation of any cultural resources avoidance or mitigation measures assigned to this project as a condition of approval for proceeding with any proposed activity. These measures may include, but are not limited to, literature searches, archaeological and American Indian monitoring, flagging or fencing to protect resources, avoidance of resource areas, archaeological testing, data recovery, evaluation of historic structures, and report preparation. If previously undocumented cultural resource items are found during excavation, grading, or other ground-disturbing activities, work would immediately cease. In addition, work would be temporarily suspended within 30 meters (100 feet) of the discovery of the cultural resources until it has been properly evaluated and
secured. Any discovery of previously unidentified cultural resources would be reported to the Vandenberg AFB Historic Preservation Officer.

The modification to LF-21 was covered in detail in the Booster Verification EA (U.S. Department of the Air Force, 1999) and the modification to LF-23 was covered in detail in the Alternate Booster Vehicle Verification Tests EA (U.S. Army Space and Missile Defense Command, 2002c). The Proposed Action would include the use of up to two GBI silos. LF-21 and LF-23 could be used with very minor modifications. LF-02, LF-03, LF-10, and LF-24 would require varying levels of modification. Modifications would include those described in section 2.3.2.1.2. Additional facilities listed in table 2.3.2-1 would also require modifications. All construction staging areas would be located on paved or previously disturbed graded areas. Modifications may be required for Buildings 1819 and 1900, as well as for LF-02, LF-03, and LF-10 described above. All of these facilities are eligible for listing on the National Register of Historic Places. Prior to the reuse of these facilities, consultation would occur with the State Historic Preservation Officer to ensure their protection or appropriate mitigation to preserve information concerning these facilities.

For communication among the components at Vandenberg AFB, the Proposed Action would maximize use of available communications assets, to include cable. If communication cable is not available, new cable would be installed in new conduits. Cable routes would be designed to avoid environmental impacts and would be approved by 30 CES/CEV. Trenching for the new communications cable/conduit would have a maximum depth of 0.91 meter (3 feet). Slant/directional drilling is also being proposed as a means of minimizing impacts to the environment if required. Installation of cable would have a localized, minimal impact on cultural resources.

**Operation**

**Flight Activities**

Proposed GBI operations for Alternative 2 at Vandenberg AFB would consist of single and dual launches of GBIs. Only in the unlikely event of flight termination over land (necessitating debris recovery within the ROI) would the possibility for impacts to cultural resources from off-road vehicle activity exist. Even then, all areas affected by ground impacts of flight hardware would be cleared of all recoverable debris in strict accordance with current Vandenberg AFB policy.

Other potential effects could result from debris striking the ground where surface or subsurface archaeological deposits are located, resulting in soil contamination, fire, and/or resource damage. The probability of this occurring, however, is considered extremely remote. Debris falling offshore would pose no threat to Vandenberg AFB's cultural resources.

Lastly, potentially adverse effects to area historic and prehistoric resources could also occur as a result of the unauthorized collection of artifacts by flight preparation personnel. Personnel would receive a brief orientation involving a definition of cultural resources and protective federal regulations.

**Post-Flight Activities**

If required, debris recovery on land may involve the use of helicopters and off-road vehicles. Recovery of missile and missile components after unsuccessful launches would be conducted in
accordance with Vandenberg AFB procedures. If the potential exists to disturb cultural resources during debris recovery activities, recovery efforts would be coordinated with Vandenberg AFB personnel to avoid impact to sensitive resources and to restore natural areas as necessary following debris recovery efforts.

4.5.3.3.2 Target Operation

Proposed target operations for Alternative 2 at Vandenberg AFB would be identical as that described for Alternative 1.

4.5.3.3.3 In-Flight Interceptor Communication System Data Terminal Construction

Proposed IDT construction for Alternative 2 at Vandenberg AFB includes a new IDT with associated roads and cables at one of six alternative locations.

The proposed IDT construction area is located very close to previously paved roads. Approximately 5.9 hectares (14.6 acres) would be disturbed during construction of the IDT. As project details are further delineated, coordination would occur with the Environmental Planning Section and the Cultural Resources Section at Vandenberg AFB to further ensure that cultural resources would be protected. Records on file at Vandenberg AFB would be consulted to determine whether sites have been identified at this location. Therefore, no archaeological resources are anticipated to be impacted. Should cultural resources be found during the course of any GMD ETR activity, all activities would cease in the area and the proper authorities would be notified. Subsequent actions would follow the guidance provided.

Operation

IDT operations are not expected to adversely impact cultural resources. The nature of the operation of these systems combined with the lack of existing cultural resources would most likely result in negligible impacts. Once again, personnel would be informed of the sensitivity of cultural resources and the types of penalties that could be incurred if sites are damaged or destroyed.

4.5.3.4 Sensors

Proposed sensor operation for Alternative 2 at Vandenberg AFB is the same as that described for Alternative 1.

4.5.3.4 Alternative 3

Alternative 3 at Vandenberg AFB would consist of a combination of both Alternatives 1 and 2.

4.5.3.5 Cumulative Impacts

Construction would occur in new locations with minimal impact and not result in cumulative impacts to cultural resources. The total area disturbed during IDT construction would be
approximately 5.9 hectares (14.6 acres), which is approximately 0.01% of the 39,821 hectares (98,400 acres) owned by Vandenberg AFB. Launches from Vandenberg AFB are limited to 30 annually (10 military launches from north Vandenberg AFB and 20 space launches). The prior EAs that analyzed GMD activities at Vandenberg AFB (U.S. Army Space and Missile Defense Command, 2002a; U.S. Department of the Air Force, 1999) indicated no cumulative impact to cultural resources for up to six GBI launches annually. Based on preliminary planning information through fiscal year 2007, the Proposed Action of up to five launches (interceptor and target), in conjunction with current planned or anticipated launches, would not exceed the 30 annual launch limit from Vandenberg AFB. Missile launches are short-term, discrete events. Activities would be performed at different times and locations, and therefore no cumulative impact to cultural resources is anticipated.

Initial defensive operations capabilities being developed at Vandenberg AFB would not include missile launches. Operations would include backup generators at four GBI LFs, and minor site preparation activities. However these actions would not result in cumulative impacts to cultural resources.

4.5.3.6 Mitigation Measures

No cultural resources mitigation measures are proposed for the GMD ETR activities at Vandenberg AFB at this time. However, once specific communication and fiber optic cable routes are identified they would be reviewed to determine if cultural resources mitigations are necessary. As project details are further delineated, coordination would occur with the Environmental Planning Section and the Cultural Resources Section at Vandenberg AFB to further ensure that cultural resources would be protected.

4.5.4 GEOLOGY AND SOILS—VANDENBERG AIR FORCE BASE

The proposed program activities have the potential to increase soil erosion during construction of IDT facilities. GBI and target missile launches could alter the chemical composition of site soils from exhaust emissions. No known geologic resources exist at any of the proposed program locations and no impacts are anticipated. Program support facilities, IDT, sensors, radar, and other critical equipment would be potentially subject to strong vibratory ground motions from moderate earthquakes.

4.5.4.1 No Action Alternative

If the No Action Alternative were selected, Vandenberg AFB would support single target launches and GBI test flights in support of GMD-related Booster Verification Tests. No additional environmental consequences would be anticipated from the GBI and target launches because Vandenberg AFB is an existing U.S. Air Force test range and, as such, routinely conducts testing similar to the GMD program. Existing environmental documentation, including the Alternate Booster Vehicle Verification Test EA (U.S. Army Space and Missile Defense Command, 2002c) and the Booster Verification Test EA (U.S. Department of the Air Force, 1999), would cover all environmental aspects of the No Action Alternative.
4.5.4.2 Alternative 1

4.5.4.2.1 Targets

Construction
The proposed activities under Alternative 1 would use existing facilities at Vandenberg AFB to support target operations; therefore, no new construction would be required, and no adverse affects to geology or soils would be expected from proposed activities.

Operation
Vandenberg AFB could support up to five target launches per year over the duration of the test program. Target missile launches could cause minor alteration of local soil chemistry as a result of exhaust emissions and debris from the launch. The potential adverse effects to soil would be minor and would be the same as that described in section 4.1.5.2.1.

There would be a potential for strong, near-field vibratory ground motion at Vandenberg AFB from seismic activity on the active Lion’s Head, Hosgri, Santa Ynez River, and Honda faults that transect Vandenberg AFB, and from other known active faults in Santa Barbara County. Movement on any of these known active faults would potentially affect the project area, as would activity along the regional San Andreas Fault System. Strong ground-shaking could promote mishaps and possible spills during storage and handling. However, the recurrence intervals for major earthquakes (magnitude 5.2 to 7.0 on the Gutenberg and Richter scale) are wide ranging, from every 14 to 115 years (U.S. Department of the Air Force 1999), and the base has not reported historic damage to its facilities from earthquakes (U.S. Department of the Air Force 1999). Although some of these faults have displayed evidence of surface rupture in the last 10,000 years, it is not expected that future earthquakes would cause surface ruptures at or directly adjacent to any of the proposed facility sites. In addition, given the periodic nature of the program testing periods, the risks to program support personnel would be minor.

4.5.4.3 Alternative 2

4.5.4.3.1 Ground-Based Interceptors

Construction
Modifications to LF-21 and LF-23, and upgrades to the Missile Assembly Building and launch control buildings, have been covered under the Alternate Booster Vehicle Verification Test EA (U.S. Army Space and Missile Defense Command, 2002c) and the Booster Verification Test EA (U.S. Department of the Air Force, 1999), which concluded no adverse effects to geology and soils would be anticipated. LF-21 and LF-23 could be used with very minor modifications. LF-02, LF-03, LF-10, and LF-24 would require varying levels of modification. Modifications would include those described in section 2.3.2.1.2. Additional facilities listed in table 2.3.2-1 would also require modifications. All construction staging areas would be located on paved or previously disturbed graded areas. Modifications to existing facilities would not cause adverse effects to geology and soils.

For communication among the components at Vandenberg AFB, the proposed action would maximize use of available communications assets, to include cable. If communication cable is not available, new cable would be installed in new conduits. Cable routes would be designed to
avoid environmental impacts and would be approved by 30 CES/CEV. Installation of cable would have a localized, minimal impact on geology and soils.

**Operation**

GBI target launches would create minor adverse affects to the site soils as a result of GBI rocket emissions. The potential effects from a nominal launch as well as possible premature termination are described in section 4.1.5.2.1.

The potential adverse effects from seismic ground shaking of GBI facilities would be the same as that described in section 4.5.4.1.

**4.5.4.3.2 Targets**

Under Alternative 2, target construction would be the same as that described for Alternative 1.

**4.5.4.3.3 In-Flight Interceptor Communication System Data Terminal Construction**

The Alternative 2 action would require new construction for an IDT and a connecting road and cables at one of six alternate locations. The probable area of soil disturbance for the site preparation activities would be approximately 5.9 hectares (14.6 acres), primarily owing to grubbing and clearing of vegetation within the perimeter fence, foundation excavation, stockpile, and equipment maneuver areas. Minor effects to soils would be likely to occur as a result of potential soil erosion, depending on the local relief and soils at the selected alternate site.

Before determining the final site layout and design standards for the IDT facilities, information bearing on seismic design and construction standards and surface faulting potential would be considered by the design engineer and geotechnical consultant.

**Operation**

Operation of the IDT at Vandenberg AFB would have no direct or indirect, short- or long-term adverse effects on site geology or soils. The potential adverse effects from seismic ground shaking of IDT facilities would be the same as those described in section 4.5.4.1.

**4.5.4.4 Alternative 3**

Alternative 3 includes all actions as described for Alternatives 2 and 3.

**4.5.4.5 Cumulative Impacts**

The existing mission of Vandenberg AFB is to conduct space and missile test activities similar to those proposed for GMD ETR. The proposed action would pose no cumulative impacts to geology and soils, with the exception of minor residual deposition of exhaust emissions from multiple launches over the duration of the program. This alteration in soil chemistry would be local and would not pose an increased risk to human health, as described in section 4.1.5.2.1.
Initial defensive operations capabilities being developed at Vandenberg AFB would not include missile launches. Operations would include backup generators at four GBI LFs, and minor site preparation activities. Adherence to established procedures would limit potential impacts and not result in cumulative impacts to geology and soils.

4.5.4.6 Mitigation Measures

Although no specific mitigation measures are proposed, standard measures for seismic safety would include special provision for proper anchoring and/or dampening of missile components and fuel canisters while in storage. Likewise, missile storage buildings and Missile Assembly Buildings would be inspected to ensure structural integrity of foundation, roof, wall connections, and storage racks to reduce risk to program personnel during a design seismic event. Before determining the final site layout and design standards for IDT facilities, information bearing on seismic design and construction standards and surface faulting potential would be considered by the design engineer and geotechnical consultant.

4.5.5 HAZARDOUS MATERIALS AND HAZARDOUS WASTE—VANDENBERG AIR FORCE BASE

This section addresses potential impacts that could result from the storage and use of hazardous materials and the generation and disposal of hazardous waste associated with launch operations from Vandenberg AFB, and construction required to support GMD launch operations. Pollution prevention, recycling, waste minimization, IRPs, USTs, ASTs, asbestos, lead-based paint, and PCBs have been considered. Potential impacts from launch activities are addressed under each alternative as applicable. A general description of impact on hazardous material and waste management is provided in the beginning of section 4.1.6.

4.5.5.1 No Action Alternative

Under the No Action Alternative, Vandenberg AFB would continue to be operated as a test area for space and missile operations. GMD-related activities such as the booster verification test flights addressed in the EA for Booster Verification Tests (U.S. Department of the Air Force, 1999) and the Alternate Booster Vehicle Verification Tests EA (U.S. Army Space and Missile Defense Command, 2002c), and single target launches would continue. No new substantive use of hazardous materials or generation of hazardous waste would occur as a result of the No Action Alternative.

4.5.5.2 Alternative 1

4.5.5.2.1 Targets

Alternative 1 would involve single and dual target launches from Vandenberg AFB. This is within the range of launches routinely performed at Vandenberg AFB, as described in chapter 2.0 and under the No Action Alternative, and no new substantive use of hazardous materials or generation of hazardous waste would occur.
Operation

Vandenberg AFB could support the proposed five target launches per year over the duration of
the test program. Existing hazardous materials and waste management procedures at
Vandenberg AFB would ensure that no adverse environmental impacts occur. MDA would be
responsible for the shipment and distribution of hazardous materials to the base. Vandenberg
AFB Safety and Environmental offices would provide guidance for the receipt and storage of
hazardous materials, and the disposal of hazardous waste generated from implementation of
Alternative 1.

Pre-Launch Activities

Pre-launch activities include transportation of target missiles to Vandenberg AFB, temporary
storage, pre-launch assembly and checkout, and preparation of the missiles for launch.

Missile components arrive at Vandenberg AFB approximately 4 to 6 weeks before launch.
Missile components would be handled and stored in accordance with applicable federal, state,
and U.S. Air Force regulations. An ESQD would be established around storage and assembly
areas based on the equivalent explosive force of propellant contained within the missile.

As discussed in section 3.5.4, hazardous materials (external to those preloaded into the
missiles) that may typically be used as part of missile launch activities include coatings,
cleaners, solvents, lubricants, and motor and diesel fuel. Most of these materials would be
consumed during use, generating minimal waste. In the unlikely event that a spill or release
occurs, the use of procedures outlined in the Vandenberg AFB SPCC Plan and Hazardous
Materials Emergency Response Plan would ensure that the potential impact would be minimal.
Target launch and launch support activities would not require additional fuel storage tanks or
hinder actions at Vandenberg AFB IRP sites.

Facility modifications associated with target launch and launch support activities at Vandenberg
AFB may disturb asbestos or lead-based paint. Management and abatement of asbestos and
lead-based paint at Vandenberg AFB would be compliant with the Vandenberg AFB Lead-
Based Paint Management Plan, Air Force Instruction (AFI) 32-1052, Facility Asbestos
Management Plan, the Vandenberg AFB Asbestos Management Plan, the Asbestos Operating
Plan, as well as the appropriate state and federal regulatory requirements and standards
referenced in appendix B. Best practices, lessons learned, and expectations indicated in the
Vandenberg AFB Lead-Based Paint Management Plan, AFI 32-1052, Facility Asbestos
Management Plan, the Vandenberg AFB Asbestos Management Plan, and Asbestos Operating
Plan would be incorporated into design and construction plans.

Launch Activities

Flight activity considerations include the Launch Hazard Area, flight corridor clearance, missile
launch, and missile impact.

An ESQD would be calculated around the launch site based on the equivalent explosive force of
all propellant and pyrotechnic materials contained within the missile. Before each launch, the
Vandenberg AFB Safety Office computes a toxic hazard corridor to ensure surrounding
communities are not at risk in the event of an anomaly. Only when meteorological conditions
indicate this corridor does not extend off the base is the operation allowed to proceed.
It is possible for a missile booster to detonate or for the propellant to burn but not explode and terminate the launch at the launch site. It is also possible for missile flight to be terminated at the point of/shortly after liftoff, or to be terminated shortly after the missile has left the launch pad. In the event of such a mishap, the incident would be handled as an explosive ordnance event. In accordance with Range Safety Requirements, EWR 17-1, an emergency response team from Vandenberg AFB would be on standby near the launch site to ensure immediate response and rapid control in the event of such an occurrence. The emergency response team would consist of Vandenberg AFB fire-fighting, safety, medical, and bio-environmental engineering personnel. Any remaining hazardous materials would be regarded as hazardous waste for management purposes. The resulting hazardous waste would be rendered safe by Explosive Ordnance Disposal personnel and disposed of in accordance with applicable federal, state, and base requirements.

If a launch is terminated after the missile has left the launch pad, then hazardous material would remain within the ESQD/evacuation zone and there would be minimal impact to personnel and no impact to the public from an accidental release. Any debris would fall within the Vandenberg AFB Test Ranges and the open ocean west of the base. Areas such as oil rigs and shipping lanes would be cleared before launch in accordance with existing Vandenberg AFB SOPs. Any debris falling on Vandenberg AFB would fall in areas cleared before launch and would be handled in accordance with Vandenberg AFB emergency response plans.

Post-Launched Activities
Post-flight activities involve check of release areas, clean-up, and transportation from Vandenberg AFB. Following test activities, the target launch facilities would be readied for the next use or placed in standby mode. Any waste would be collected and segregated as nonhazardous, hazardous, and possibly special wastes for proper disposal in accordance with federal, State of California, and DoD requirements. Specific restoration actions, if necessary, would be determined on a case-by-case basis in coordination with the procedures of the Facility Services Division of Hazardous Materials.

4.5.5.3 Alternative 2
Alternative 2 would consist of activities described in the No Action and Alternative 1 except as noted herein. Single and dual launch of GBI missiles would also occur under Alternative 2. GBI-related activities would include support facility modification, and IDT construction and operation. Hazardous materials use and hazardous waste generation would be managed as described in section 3.1.6.

4.5.5.3.1 Ground-Based Interceptor

Construction
The modification of LF-21 and LF-23 to support GBI launches, and the modification of associated facilities to be used at Vandenberg AFB was analyzed in the Booster Verification EA and the Alternate Booster Vehicle EA and determined to cause no significant impacts to hazardous materials and hazardous waste. The Proposed Action would include the use of up to two GBI silos. LF-21 and LF-23 could be used with very minor modifications. LF-02, LF-03, LF-10, and LF-24 would require varying levels of modification. Modifications would include those described in section 2.3.2.1.2. Additional facilities listed in table 2.3.2-1 would also require
modifications. The staging areas for any construction materials and equipment associated with the modification of the missile launch silos or buildings would be paved. Since some of the facilities proposed for use were constructed in a period during which lead-based paint was used as exterior and interior coating and asbestos was used in equipment and construction materials, the minor modifications planned could result in disturbance of exterior or interior surfaces.

Prior to the initiation of any construction/structural modification, the contractor responsible for facility modifications would perform surveys and sampling for lead-based paint, asbestos and PCBs using applicable federal, state regulations, the Vandenber AFB Lead-Based Paint Management Plan, AFI 32-1052, Facility Asbestos Management, the Vandenber AFB Asbestos Management Plan, the Asbestos Operating Plan, the Vandenber AFB PCB Management Plan and the Vandenber AFB Hazardous Waste Management Plan. Any removal/abatement or disposal of these hazardous wastes would be conducted in accordance with applicable federal and state regulations, and the referenced AFI and Vandenber AFB management plans and requirements. Therefore, there is a low likelihood of the potential release of lead-based paint, asbestos, or PCBs.

The potential installation of new conduit and fiber optic cable would not likely result in the release of a potentially hazardous material or waste.

Missile components would be handled and stored in accordance with applicable federal and state, and U.S. Air Force regulations as discussed in section 3.5.4 and under the No Action Alternative and Alternative 1. No onsite fueling of the GBI would be required. No release or spills of hazardous materials would be expected as a result of pre-launch operations.

Operation

GBI launch operations would be conducted as described in section 4.1.6. The proposed launch of GBIs from Vandenberg AFB is not expected to substantially increase the volume of hazardous materials used, or hazardous waste generated, at Vandenberg AFB. MDA would be responsible for the shipment and distribution of hazardous materials to the base. Transportation and handling of missile components are discussed in section 2.3.2. Vandenberg AFB Safety and Environmental Offices or the MDA contractor would be responsible for the receipt and storage of hazardous materials, and the disposal of hazardous waste.

4.5.5.3.2 In-Flight Interceptor Communication System Data Terminal

Hazardous materials use would be minimal for IDT construction and operation and would consist of corrosion control materials (e.g., paints) and low-toxicity cleaning products. These materials are routinely used at Vandenberg AFB and would be handled in compliance with applicable federal, state, and base regulations and requirements.

4.5.5.4 Alternative 3

The proposed actions and potential impacts would be the same as those described under Alternatives 1 and 2.
4.5.5.5 Cumulative Impacts

Construction would occur in new locations with minimal impact and not result in cumulative impacts to hazardous waste and hazardous materials management. Launches from Vandenberg AFB are limited to 30 annually (10 military launches from north Vandenberg AFB and 20 space launches). The prior EAs that analyzed GMD activities at Vandenberg AFB (U.S. Army Space and Missile Defense Command, 2002c; U.S. Department of the Air Force, 1999) indicated no cumulative impact to hazardous materials and waste management for up to six GBI launches annually. Based on preliminary planning information through fiscal year 2007, the Proposed Action of up to five launches (interceptor and target), in conjunction with current planned or anticipated launches, would not exceed the 30 annual launch limit from Vandenberg AFB. Adherence to the hazardous materials and waste management systems on Vandenberg would preclude the accumulation of hazardous materials or waste, and therefore no cumulative impact to hazardous material or hazardous waste management practices is anticipated at Vandenberg AFB.

Initial defensive operations capabilities being developed at Vandenberg AFB would not include missile launches. However, operations would include backup generators at four GBI LFs, and minor site preparation activities. These actions would also adhere to hazardous materials and waste management systems on Vandenberg and not result in cumulative impacts.

4.5.5.6 Mitigation Measures

No hazardous waste/hazardous materials management mitigation measures are proposed for the GMD ETR activities at Vandenberg AFB.

4.5.6 HEALTH AND SAFETY—VANDENBERG AIR FORCE BASE

4.5.6.1 No Action Alternative

Under the No Action Alternative, single target launches would occur at Vandenberg AFB. Regional safety programs would be the same as safety programs for current launch systems as described in section 3.5.5. Potential issues related to health and safety would be associated with pre-launch, launch, and post-launch activities. Planning and execution of target launches would be in compliance with federal, state, local, and range health and safety requirements. Therefore, no increase in risk to health and safety would be expected as a result of implementing this alternative.

4.5.6.2 Alternative 1

4.5.6.2.1 Target

Construction

Existing launch facilities, support facilities, and equipment would be utilized for the target launches. No construction or facility modification would be necessary under this alternative. Therefore, no increase in potential impact to health and safety would be expected from construction activities.
Pre-Launch Activities

Launch preparation activities would consist of transportation and storage of the booster/launch vehicle, target re-entry vehicle, missile components, and support equipment to Vandenberg AFB. Transportation of missile components would be accomplished by aircraft or over road by truck in compliance with applicable state, federal, and U.S. Air Force safety regulations. Hazardous materials and explosives would be packaged in shipping containers designed according to DOT requirements to protect against release in the event of an accident. All containers would have proper placards, and only carriers licensed to handle/transport hazardous materials would be utilized. These transportation procedures would minimize the potential for accidents, as well as provide the means of mitigating potential adverse effects should an accident occur. Therefore, no health and safety effects to the general public or to military and government-employed civilians working on the base are anticipated.

Storage areas would be fenced, and appropriate placards would be used. Access would be limited to mission critical personnel. All personnel associated with the Proposed Action, including material storage, would be properly trained in compliance with 29 CFR 1910 procedures and other applicable state and federal regulations and guidelines. However, the handling and assembly of missile components, accomplished within enclosed areas, has the potential to affect worker health and safety training; adherence to appropriate safety regulations and operating plans and protocol would serve to maintain potential health and safety risks to mission personnel within acceptable levels. Since public access to Vandenberg AFB is limited, and since ESQDs would be established around storage areas and Buildings 1855 and 6816, no impact to public health and safety would be expected.

Launch Activities

Compliance with launch safety regulations would be provided through 30 SW/CCC, 30 SW/SE, and the Mission Flight Space Control Officer. A written procedure for all explosive pre-launch activities is required and must be approved by 30 SW/SE. An ESQD would be established around the launch site because of the potential for missile malfunction during a launch. Established procedures to prohibit access to restricted areas would be followed. The restricted areas are based upon the probability of potential hazards involved with malfunction during test flights and would include:

- The impact limit line, which sets the boundary of the protection line for all non-mission-essential personnel
- The launch caution corridor, an area limited to essential personnel
- The Launch Hazard Area, an area around the launch point limited to essential personnel in hardened facilities (approximately 20 essential personnel in the Launch Control Center)
- The stage impact area

For impact limit lines that extend beyond Vandenberg AFB boundaries, an agreement would be made with the appropriate landowners to control the use of these areas during launches. The 30 SW/SE and the 30th Range Squadron Airspace and Offshore Management Section (for offshore oil rigs) would oversee evacuations of surrounding land and water users.
An emergency response team, consisting of fire fighting, safety, medical, and bio-environmental engineering personnel, would be near the proposed project site during launch activities. Additional Vandenberg AFB personnel and resources would be called out if needed. Emergency response would also be provided through local county entities, if needed. The range of acceptable launch azimuths for a Minuteman II from LF-23 was between 260 degrees and 280 degrees. The final range of approved azimuths for target launches would be determined after submittal of the preliminary flight data package, which defines the proposed launch azimuth and all launch vehicle performance characteristics for the proposed launch vehicle configuration. The azimuth would be limited to ensure that potential missile failure would not result in debris outside the azimuthal boundary. Final launch azimuth boundaries would be established after all vehicle performance data and areas of endangerment are reviewed, and Flight Termination System requirements are established.

Target launches would take place in either existing restricted areas or warning area airspace that would be cleared of non-participating aircraft. The launches would be short-term events, after which joint-use airspace would be released to other users; advance scheduling would obviate impacts. The Flight Safety Analyst from 30 SW/SE would define which airspace areas would potentially be affected by the Proposed Action and the Chief of Range Operations would coordinate with the FAA and the U.S. Coast Guard to identify and address any issues of concern. No additional impacts would occur to airspace as a result. With the implementation of the appropriate safety regulations and approvals and coordination with 30 SW/SE, the target launches would not be expected to present a substantial impact to the health and safety of base workers and personnel or the public.

The Western Range has a three-tiered, three-zone deterministic approach plus a probabilistic approach to protecting against harmful toxic exposures of hydrogen chloride. The Western Range implements safety measures that are designed to protect mission essential and non-mission essential persons. Before launch, the Rocket Exhaust Effluent Diffusion Model is used to locate toxic zones.

There are three zones for assessing an individual’s proximity to toxic combustion products, including those that could result from a launch failure. Zone 1 is an area where airborne concentrations of any toxic product are equal to or exceed Tier 1 levels (2 ppm) but are less than Tier 2 levels (10 ppm). Zone 2 is an area where airborne concentrations of any toxic product are equal to or exceed Tier 2 levels (10 ppm) but are less than Tier 3 levels (50 ppm). Zone 3 is an area where airborne concentrations of any toxic product range from a low defined by Tier 3 (50 ppm) to an unknown high. Table 3.5.6-1 describes the Tier levels.

Before launch, the Rocket Exhaust Effluent Diffusion Model is run to ensure that any mission essential persons within a Zone 2 (having predicted hydrogen chloride concentrations exceeding the Tier 2 level [see 30 SWI 91-106, 1998]) are aware of being in a Zone 2, have personnel protection equipment, and have a pre-determined route of departure. If mission essential personnel do not meet these requirements, then they are relocated out of the zone. Any non-mission essential people on-base are also moved, if feasible. If they cannot be moved, or if they are off-base and not subject to being moved, then their locations and exposure are taken into account in the risk assessment procedure.

The Western Range toxic risk-assessment-based recommendation to launch or not to launch is based on the results of the LATRA program (i.e., risk assessment program) that evaluates the
risk to people, regardless of whether they are mission essential or non-mission essential. Among other criteria in determining whether to launch, the LATRA accounts for (1) whether people are sheltered or unsheltered; (2) whether they are healthy or sensitive individuals; and (3) the probability of a catastrophic launch failure.

Post-Launch Activities

Minor facility maintenance would occur after each launch to ensure that the launch site would be operational for the next test. Post-launch procedures would include silo inspection, removal of blast residue, and minor silo refurbishing. Any blast residue generated from the launch would remain within the launch silo and the missile canister. Entry to the silo would be restricted to trained and approved personnel in proper protective equipment. The blast residue would be removed, collected, and properly disposed of according to 40 CFR, California Code of Regulations Title 22, and the Vandenberg AFB Hazardous Waste Management Plan. Should the residue be identified as hazardous, there would be no impact to the health and safety of base personnel or the public.

4.5.6.2.2 Sensors

Sensor operation would continue at current levels. No increased impact to health and safety would be expected as a result of implementing Alternative 1 at Vandenberg AFB.

4.5.6.3 Alternative 2

4.5.6.3.1 Ground-Based Interceptor

Construction

The modification of LF-21 and LF-23 to support GBI launches, and the modification of associated facilities to be used at Vandenberg AFB was analyzed in the Booster Verification EA and the Alternate Booster Vehicle EA and determined to cause no significant safety related impacts. The proposed action would include the use of up to two GBI silos. LF-21 and LF-23 could be used with very minor modifications. LF-02, LF-03, LF-10, and LF-24 would require varying levels of modification. Modifications would include those described in section 2.3.2.1.2. Additional facilities listed in table 2.3.2-1 would also require modifications. Any facility modifications would comply with OSHA, U.S. Air Force safety and health regulations, Range Safety Requirements, and other recognized standards for operations that involve construction. Restricted public access to the proposed project site would be ensured through use of signs and fencing. A health and safety plan would be prepared by the contractor and submitted to the base to ensure the health and safety of onsite workers. A formally trained individual would be appointed to act as safety officer. The appointed individual would be the point of contact on all problems involving job site safety. During performance of work, the contractor must comply with all provisions and procedures prescribed for the control and safety of construction team personnel and visitors to the job site. Compliance with regulations would ensure that no health and safety impacts would result from the silo and building modification.

Operation

Pre-launch, launch, and post-launch activities would generally occur as discussed in section 4.5.4.3.1. No increased impact to health and safety would be expected.
4.5.6.3.2 Target

Construction
Construction of a target launch pad would generally occur as discussed in section 4.5.4.3.1. Adherence to base safety plans and procedures would ensure no increased risk to health and safety.

Operation
Pre-launch, launch, and post-launch activities would generally occur as discussed in section 4.5.4.2.1. No increased impact to health and safety would be expected.

4.5.6.3.3 In-Flight Interceptor Communication System Data Terminal

Construction
Adherence to base safety plans and procedures would ensure no increased risk to health and safety.

Operation
Adherence to base safety plans and procedures would ensure no increased risk to health and safety.

4.5.6.3.4 Sensors

Sensor operation would continue at current levels. No increased impact to health and safety would be expected as a result of implementing Alternative 2 at Vandenberg AFB.

4.5.6.4 Alternative 3

Implementation of Alternative 3 would include all of the components Alternative 1 and Alternative 2. Therefore, no increase in potential risk to health and safety would be expected as a result of selecting this alternative.

4.5.6.5 Cumulative Impacts

Adherence to Vandenberg AFB safety plans and procedures would preclude potential cumulative impacts to health and safety resulting from the implementation of the GMD ETR. Initial defensive operations capabilities being developed at Vandenberg AFB would not include missile launches. However, operations would include backup generators at four GBI LFs, and minor site preparation activities. These actions would also adhere to Vandenberg AFB safety plans and procedures and not result in cumulative impacts. Based on Vandenberg AFB SOPs and other activities in the area, there is minimal potential for cumulative health and safety risk to the public from operations at Vandenberg AFB.

4.5.6.6 Mitigation Measures

No health and safety mitigation measures are proposed for the GMD ETR activities at Vandenberg AFB.
4.5.7 LAND USE—VANDENBERG AIR FORCE BASE

4.5.7.1 No Action Alternative

Under the No Action Alternative, the GMD ETR would not be established and interceptor and target launch scenarios would not be tested under operationally realistic conditions. Activities and facilities involved in GBI booster verification launches, single target missile launches, and radar operation would continue and would not change Vandenberg AFB’s general land use. Adjacent lands that exhibit open-type agricultural uses with no development would continue to be compatible with the requirements of Vandenberg AFB. Planning and execution of launches would be in total compliance with federal, state, local, and range land use requirements. Therefore, adverse impacts to the land use would not be expected under the No Action Alternative.

The continuation of activities at Vandenberg AFB is compatible with the California CZM Program under the No Action Alternative. Under the No Action Alternative, closures of recreational areas and adjacent parks would continue during periods of hazardous operation. To minimize the land use conflicts, Vandenberg AFB extensively publicizes Launch Hazard Areas. Coastline, beach, and recreational area availability would continue to be made known to the public through various local media sources. Furthermore, similar coastal opportunities are not unique to Vandenberg AFB and are provided elsewhere along the coast.

4.5.7.2 Alternative 1

Under Alternative 1, Vandenberg AFB would conduct single and dual target missile launches and sensor support facilities.

4.5.7.2.1 Target

Construction

Existing launch facilities, support facilities and equipment would be utilized for the target launches. No construction or facility modification would be necessary under this alternative. Therefore, activities would be accomplished completely within the compatible existing locale for such use and would not produce an adverse impact involving land use.

Operation

Pre-Launch Activities

Pre-launch activities would involve the transportation and storage of missile components and support equipment to Vandenberg AFB. All missile components and support would be handled, labeled, and stored in accordance with all pertinent FAA, DOT, OSHA, and U.S. Air Force safety regulations for transportation by air and/or over land by trucks. Regulations would minimize the potential for adverse impacts to land use and provide a means of mitigating adverse effects should an improbable mishap occur.

Storage of target missiles and their propellants would occur in separate existing storage areas designed for such use in accordance with all accepted governing standards. ESQDs would be established and maintained around storage facilities.
Before each launch, the target missile and necessary components would be moved from storage to a Missile Assembly Building where it would be assembled and checked before being transported to the launch pad. Transportation of assembled target missiles would use on-base roads. Although temporary on-base closures would cause a land use impact to traffic, closures would be of short duration and considered normal base activity.

**Flight Activities**

Launch preparations scheduled at Vandenberg AFB would follow standard evacuation procedures of the launch vicinity. During the time the target missile booster is on the launch pad, potential impacts to land use could occur. Land areas that are within the Launch Hazard Area would be cleared approximately 1 hour before launch and guarded to ensure they remain clear of all non-mission personnel. A Notice of Intent to clear hazardous areas would be published in the local newspaper and broadcast in local media. Clearance and closures are considered normal operations and would be determined by necessary pre-launch missile Launch Hazard Area determinations and flight corridor clearances.

Under Alternative 1, no new Launch Hazard Area would be created or extended that would violate existing or off-base land uses. Launch operations would utilize the already existing LF-6 or its alternate LF-3 launch silos. Potential impacts to the California Coastal Zone would be the same as determined for the No Action Alternative.

Only a preflight or early flight malfunction resulting in flight termination within the ROI would have any impact on Vandenberg AFB. In the unlikely event of an early flight termination within the boundaries of Vandenberg AFB, target missile and/or debris recovery would follow applicable environmental regulations and range procedures as directed by the Range Safety Officer to minimize impacts on land use by the increase number of activities.

**Post-Flight Activities**

As soon as the Range Safety Officer concludes that all hazardous areas are safe, all non-mission essential personnel would be allowed to return. Post-flight activities would also include removal of blast residue from the launch pad or silo and other minor facility maintenance. These activities would be confined to areas currently used for similar launch activities having no affect on land use.

4.5.7.3 Alternative 2

Under Alternative 2, Vandenberg AFB would conduct single and dual GBI and target missile launches and operate necessary IDT and sensory support facilities.

4.5.7.3.1 Ground-Based Interceptors

**Construction**

The modification of LF-21 and LF-23 to support GBI launches, and the modification of associated facilities to be used at Vandenberg AFB was analyzed in the Booster Verification EA and the Alternate Booster Vehicle EA and determined to cause no significant impacts to land use. The proposed action would include the use of up to two GBI silos. LF-21 and LF-23 could be used with very minor modifications. LF-02, LF-03, LF-10, and LF-24 would require varying
levels of modification. Modifications would include those described in section 2.3.2.1.2. Additional facilities listed in table 2.3.2-1 would also require modifications. All construction staging areas would be located on paved or previously disturbed graded areas. Modifications would be accomplished completely within the compatible existing locale for such use and would not produce an adverse impact involving land use.

For communication among the components at Vandenberg AFB, the Proposed Action would maximize use of available communications assets, to include cable. If communication cable is not available, new cable would be installed in new conduits. Cable routes would be designed to avoid environmental impacts and would be approved by 30 CES/CEV. Installation of cable would not have an adverse impact on land use.

**Operation**

Under Alternative 2, pre-launch, flight, and post-flight activities of GBI missiles would be similar to the operation of target missiles in section 4.5.6.2.1.

### 4.5.7.3.2 Target

Under Alternative 2, activities involving target missiles at Vandenberg AFB would include all actions and pose the same potential impacts mentioned under Alternative 1 in section 4.5.6.2.

### 4.5.7.3.3 In-Flight Interceptor Communication System Data Terminal

The construction and operation of a fixed, relocatable, or mobile IDT at Vandenberg AFB would require an area of approximately 5.9 hectares (14.6 acres). The IDT site would include several facilities with commercial electrical power, site backup electrical generation, all-weather access road, security fencing, and water and sewer services. The proposed IDT locations are shown on figure 2.3.2-1 and include Tracking E, Titan, Have Stare, Doppler, Borrow Pit, and Talo Road. Construction at any of the proposed locations would be routinely accomplished and the facility would exist within an area compliant with Vandenberg AFB’s overall general land use. Likewise, no conflicts with land use would occur. Furthermore, safety precautions would be followed during operation to prevent any unidentified land use conflicts from arising.

**Operation**

*Pre-Launch Activities*

IDT components would be transported to the operation site from U.S. Government storage depots or contractor facilities by air, sea, or over land by trucks. Delivery would be conducted under routine procedures in accordance with applicable FAA and DOT safety standards to minimize any possible impacts to land use.

*Flight Activities*

Although operation of IDT facilities would only function during times of GMD exercises, installation would immediately be established and secured after delivery, limiting the access to the surrounding area. This would result in a change in land use within the immediate operation area by restricting access to unauthorized personnel. However, all impacts to land use were considered in the facilities site selection and would not decrease land utilization nor change the general land use within or outside the boundaries of Vandenberg AFB.
Post-Flight Activities
Post-flight operation would include the standard maintenance procedures to secure the IDT facilities and preparation for possible relocation of the transportable IDT. Procedures would be confined to areas already used for the establishment of such facilities and would not change or introduce a conflicting use of land within the vicinity.

4.5.7.4 Alternative 3
Under Alternative 3, GMD activities would include all actions and pose the same potential impacts as described in Alternatives 1 and 2.

4.5.7.5 Cumulative Impacts
Since the proposed activities would be compatible with existing Vandenberg AFB land use plans and policies, the potential for cumulative impacts with existing activities are avoided. Initial defensive operations capabilities being developed at Vandenberg AFB would not include missile launches. However, operations would include backup generators at four GBI LFs, and minor site preparation activities. These actions would also adhere to Vandenberg AFB land use plans and policies and not result in cumulative impacts.

Recreational activities along the Vandenberg AFB’s coast and recreational areas are only available to the public during times of non hazardous operations. The proposed GMD launches would be encompassed in the yearly planning for intercontinental ballistic missile launches at Vandenberg AFB. Furthermore, similar coastal opportunities are not unique to Vandenberg AFB and are provided elsewhere along the coast.

4.5.7.6 Mitigation Measures
No land use mitigation measures are proposed for the GMD ETR activities at Vandenberg AFB.

4.5.8 NOISE—VANDENBERG AIR FORCE BASE
This section is concerned with the potential impacts due to construction and operation of the GBI, target, and sensor elements of the GMD ETR on the regional noise environment at Vandenberg AFB. Also identified are the potential cumulative impacts and possible mitigation measures.

Noise impacts to wildlife are addressed in section 4.5.2.

4.5.8.1 No Action Alternative
The No Action Alternative would not change the level of noise at Vandenberg AFB. Existing facilities already in use would continue, and the GMD ETR would not be established. The GBI and target launch scenarios would not be tested under operationally realistic conditions.
4.5.8.2 Alternative 1

4.5.8.2.1 Targets

Construction

Construction activities involved in the building and silo modification for target launches for Alternative 1 would be minor at Vandenberg AFB. Current facilities would be used and minor interior and software alterations would be made. Noise impacts to the surrounding environment would be minor.

Operation

Pre-Launch Activities

Noise from launch preparation, including silo and building modifications, would comply with the Occupational Safety and Health Act, the U.S. Air Force Occupational Safety and Health regulations, Range Safety Requirements, and other recognized standards for operations that involve construction or facility modifications. Restricted public access to the proposed project site would be ensured through use of signs and fencing. A health and safety plan requiring the use of hearing protection when appropriate would be prepared by the contractor and submitted to the base to ensure the health and safety of onsite workers.

Launch Activities

OSHA has established noise limits to protect workers at their work places. According to these standards, no worker can be exposed to noise levels higher than 115 dBA. The exposure level of 115 dBA is limited to 15 minutes or less during an 8-hour work shift (U.S. Air Force 1992). The OSHA standards are the maximum allowable noise levels for the personnel in the vicinity of the launch pad. Workers exposed to excessive launch noise would be required to wear hearing protection.

Noise from missile launches can range from 60 to 100 dBA in the vicinity of the launch including areas near Lompoc and Santa Maria. The noise from a Minuteman launch is 80 dBA approximately 13 kilometers (8 miles) from the launch site. Figure 4.5.7-1 depicts noise levels for a Minuteman launch from Vandenberg AFB. However, because the launches occur infrequently, the resulting noise has little impact on the L_{eq} or CNEL in these areas. Therefore, ambient noise levels would not be affected substantially on an annual basis from the proposed GMD ETR tests. Noise impacts would also be short in duration.

Since the flight pattern of a target launch would be over the open ocean to the west, the flight would not cross populated areas such as nearby Lompoc or Santa Maria. Therefore, impacts from noise to populated areas would be minor. Noise impacts from prior Vandenberg AFB missile launches have been determined to be short term and therefore insignificant. Based on these results and compliance with regulations, the proposed launches would not cause or contribute to noise impacts.

Post-Launch Activities

Noise generated during the removal of all mobile equipment/assets should have minimal impact to the noise environment.
No substantial noise would be expected from post-launch activities. However, any noise would likely fall within or below the noise level measurements of post-launch noise associated with the previously approved Minuteman launch vehicles. Noise impacts would also be short in duration. Post-launch activities would not cause or contribute to noise impacts.

4.5.8.3 Alternative 2

4.5.8.3.1 Ground-Based Interceptors

Construction
The modification of LF-21 and LF-23 to support GBI launches, and the modification of associated facilities to be used at Vandenberg AFB was analyzed in the Booster Verification EA and the Alternate Booster Vehicle EA and determined to cause no significant noise impacts. The proposed action would include the use of up to two GBI silos. LF-21 and LF-23 could be used with very minor modifications. LF-02, LF-03, LF-10, and LF-24 would require varying levels of modification. Modifications would include those described in section 2.3.2.1.2. Additional facilities listed in table 2.3.2-1 would also require modifications. All construction staging areas would be located on paved or previously disturbed graded areas.

Noise from launch preparation, including silo and building modifications, would comply with the Occupational Safety and Health Act, the U.S. Air Force Occupational Safety and Health regulations, the U.S. Army Corps of Engineers Safety and Health Requirements Manual (EM 385-1-1), Range Safety Requirements, and other recognized standards for operations that involve construction or facility modifications. Restricted public access to the proposed project site would be ensured through use of signs and fencing. A health and safety plan, requiring the use of hearing protection when appropriate would be prepared by the contractor and submitted to the base to ensure the health and safety of onsite workers.

Operation

Pre-Launch Activities
Noises produced during pre-launch activities include noise from mechanical equipment such as worker vehicles and trucks and by the use of the public address systems. Transportation noise would increase as launch support personnel drive to the site and additional trucks bring material to the site.

Launch Activities
All public, civilian, and nonessential personnel would be required to be outside of the ground hazard area where the expected noise levels would be below the 115-dBA limit for short-term exposure.

Personnel would normally be at the Launch Control Center during launches. Although no standards exist for single-event noise exposure, a time-weighted average of 90 dBA is established as a limit for an 8-hour exposure. However, workers exposed to excessive launch noise would be required to wear hearing protection.
The GBI launch noise level is expected to fall within or below the noise level of previously measured Minuteman III launches. Figure 4.5.8-1 depicts the noise levels produced during a Minuteman III launch as well as a Peacekeeper from Vandenberg AFB. Figure 4.5.8-2 depicts the noise levels calculated for a dual launch from the single launch data. Dual launches are expected to occur virtually simultaneously. It is anticipated that noise impacts for dual launches would also fall within OSHA limits.

The flight patterns of GBI launches would be over the open ocean area and would not cross populated areas. Noise impacts form prior Vandenberg AFB launches have been previously determined to be short-term and insignificant. Based on these results and compliance with regulations, the proposed launches would not cause or contribute to noise impacts.

In addition to the noise of the rocket engine, sonic booms are possible. However, GBI launches would be in a western direction and would not occur over land. They are not expected to impact Vandenberg AFB or surrounding communities. Vessels impacted by sonic booms would be expected to experience sound resembling mild thunder.

During operations, it is estimated that up to 300 personnel would be involved in supporting a dual launch. The increase in noise associated with these personnel traveling to and from Vandenberg AFB is expected to be a minor impact.

**Post-Launch Activities**

Noise generated during the removal of all mobile equipment/assets should have minimal impact to the noise environment.

**4.5.8.3.2 Targets**

Under Alternative 2, construction and operation of target facilities and target launches from Vandenberg AFB would be the same as those described in section 4.5.6.3.2 for Alternative 1.

**4.5.8.3.3 In-Flight Interceptor Communication System Data Terminal**

Construction and operation of an IDT at Vandenberg AFB would have minimal impact to the surrounding environment’s noise levels. Construction noises would include noise from mechanical equipment. Noises involving traffic increases are included in analysis for GBI construction.

**4.5.8.4 Alternative 3**

Construction and operation of GBI facilities, target facilities, GBI launches, target launches, and range radars for Alternative 3 would be the same as those described in Alternative 1.

4.5.8.5 Cumulative Impacts

Since the sound level generated by each launch is a short, discrete event, the potential cumulative impacts to noise from GMD ETR launches would not be substantial. It is not likely that the Proposed Action, in conjunction with current planned or anticipated launches, would result in cumulative noise impacts.

Initial defensive operations capabilities being developed at Vandenberg AFB would not include missile launches. The operation of backup generators at each LF would be similar to those described above for the IDT, and would not result cumulative impacts.

4.5.8.6 Mitigation Measures

No noise mitigation measures are proposed for the GMD ETR activities at Vandenberg AFB.

4.5.9 SOCIOECONOMICS—VANDENBERG AIR FORCE BASE

4.5.9.1 No Action Alternative

Under the No Action Alternative, the GMD ETR would not be established and interceptor and target launch scenarios would not be tested under operationally realistic conditions. The activities at Vandenberg AFB would continue their current operations. No significant socioeconomic impacts from the No Action Alternative would occur.

4.5.9.2 Alternative 1

Under the implementation of Alternative 1, target launches would occur from Vandenberg AFB.

4.5.9.2.1 Target Operation

Target missile components would be built in contractor facilities and delivered to Vandenberg AFB via air or road for system assembly and checkout. Target launch facilities would include existing launch pads/silos, Missile Assembly Building, missile storage, maintenance and storage, and target launch. There would be up to five missile launches per year. Integration and assembly operations would be performed onsite. A typical ramp up over a 3-month period would be 25, 75, and 150 personnel who would be required to support a target launch. After a launch, a portion of these personnel would immediately depart Vandenberg AFB.

As part of pre-launch and flight activities, a Launch Hazard Area would be established around the launch site. The Launch Hazard Area would result in certain areas of Vandenberg AFB being cleared of personnel in the event of an accident during interceptor launch. Similarly, certain sea-surface areas would also have to be cleared. While the closure areas in question are significant in size, their nature is decidedly temporary; land areas would need to be cleared approximately 1 hour before a launch, with sea surface areas cleared approximately 4 hours before a launch. The actual launch is expected to last approximately 30 minutes. Upon the Range Safety Officer declaring the area safe after a launch, expected to be within hours, the areas can then be reoccupied. Also, the notice given to the local communities via local
newspapers, broadcast media, and commercial fishing and tourist boat trade associations would be extensive. As such, entities with an economic interest in the use of these areas such as the commercial fishing and tourist industries would not be significantly impacted by the proposed clearance areas.

For a dual target launch, up to 175 support personnel would be housed in motels or hotels within the surrounding cities of Vandenberg AFB during the operational phase of the launch. Activities related to the implementation of Alternative 1 would not cause any displacement of populations, residences, or businesses within the areas surrounding Vandenberg AFB. As outlined in section 3.5.8, there are numerous hotels and motels situated within the surrounding cities of Lompoc, Santa Maria, and Guadalupe, and the availability of temporary accommodation is considered to be adequate.

By spending money in the local economy, mainly via accommodation and procurement of goods and services, the additional personnel would represent both a potential increase in local service-based employment opportunities and a small but positive temporary economic impact to the local communities. The overall impact would, however, be slight and would not cause any population growth. No significant impacts to locally significant businesses or industries such as services, agriculture or manufacturing are anticipated during operational activities. No significant socioeconomic impacts would occur through the construction activities associated with Alternative 1.

4.5.9.2.2 Sensors

Operation

Instrumentation associated with the launch of a target missile would include existing range control radar and telemetry equipment.

The personnel associated with the launch of a target missile would operate these systems; therefore, no additional personnel other than those associated with a target launch would be needed to operate the sensors and the extent of the related economic impacts would remain the same. The proposed activities would not cause any population growth or displacement of populations, residences, or businesses within the areas surrounding Vandenberg AFB. Similarly, no significant impacts to businesses or industries are anticipated. No significant socioeconomic impacts would occur through the operational activities associated with Alternative 1.

4.5.9.3 Alternative 2

Under the implementation of Alternative 2, GBI launches would be from Vandenberg AFB instead of KLC. The GBI would require construction of an IDT and modifications to existing support facilities at Vandenberg AFB. The other components described in Alternative 1, including the launch of target missiles, would remain the same.
4.5.9.3.1 Ground-Based Interceptor

Construction
The modification of LF-21 and LF-23 to support GBI launches, and the modification of associated facilities to be used at Vandenberg AFB was analyzed in the Booster Verification EA and the Alternate Booster Vehicle EA and determined to cause no significant environmental impacts. The proposed action would include the use of up to two GBI silos. LF-21 and LF-23 could be used with very minor modifications. LF-02, LF-03, LF-10, and LF-24 would require varying levels of modification. Modifications would include those described in section 2.3.2.1.2.

By spending money in the local economy, mainly via accommodation and procurement of goods and services, the construction personnel would represent a small but positive temporary economic impact to the local community. Given that construction activities are limited and short-term, the overall impact would be slight and would not cause any significant impacts to local businesses or industries. No significant socioeconomic impacts would occur through the construction activities associated with Alternative 2.

Operation
The impact from the launch of interceptor missiles would be similar to the impact from the launch of target missiles. There would be up to five missile launches per year (combined interceptor and target). Integration and assembly operations would be performed onsite. A typical ramp up over a 3-month period would be 65, 150, and 300 personnel who would be required to support a launch. After a launch, a portion of these personnel would immediately depart Vandenberg AFB.

By spending money in the local economy, mainly via accommodation and procurement of goods and services, the additional personnel would represent both a potential increase in local service-based employment opportunities and a small but positive temporary economic impact to the local communities. The overall impact would be slight and would not cause any population growth. No significant impacts to locally significant businesses or industries such as services, agriculture or manufacturing are anticipated during operational activities. Activities related to the implementation of Alternative 2 would not cause any displacement of populations, residences, or businesses within the areas surrounding Vandenberg AFB. No significant socioeconomic impacts would occur through the operational activities associated with Alternative 2.

4.5.9.3.2 In-Flight Interceptor Communication System Data Terminal

Construction
Implementation of Alternative 2 would result in the construction of an IDT on Vandenberg AFB. One COMSATCOM would be used as part of the IDT. Approximately 35 construction personnel and related construction equipment and would be involved in the construction of the IDT.

Construction activities related to the implementation of Alternative 2 would not cause any displacement of populations, residences, or businesses. The presence of the construction personnel represents both a potential increase in local service based employment opportunities and a small but positive temporary economic impact to the local community. The overall impact would, however, be slight and would not cause any population growth. No significant impacts to
businesses or industries are anticipated during construction activities. No significant socioeconomic impacts would occur through the construction activities associated with Alternative 2.

Operation
An IDT site would require approximately 10 permanent onsite support personnel when in operation. When not in operation, the onsite backup generators would be tested for approximately 200 hours per year. The personnel associated with the IDT would be part of the approximately 300 people required to support an interceptor launch and the extent of the related economic impacts would remain the same. The proposed activities would not cause any population growth or displacement of populations, residences, or businesses within the areas surrounding Vandenberg AFB. Similarly, no significant impacts to businesses or industries are anticipated. No significant socioeconomic impacts would occur through the operational activities associated with Alternative 2.

4.5.9.4 Alternative 3
Alternative 3 would combine activities proposed for Alternatives 1 and 2 and would result in impacts that are similar to those discussed under Alternative 1 and Alternative 2.

4.5.9.5 Cumulative Impacts
Based on preliminary planning information for fiscal year 2002 through fiscal year 2007, the Proposed Action of up to five launches (interceptor and target), in conjunction with current planned or anticipated launches would not exceed the current limit of 30 launches per year. The addition of the GMD ETR launches to the identified ongoing and future programs in the ROI would result in a positive cumulative socioeconomic impact.

4.5.9.6 Mitigation Measures
No socioeconomic mitigation measures are proposed for the GMD ETR activities at Vandenberg AFB.

4.5.10 TRANSPORTATION—VANDENBERG AIR FORCE BASE

4.5.10.1 No Action Alternative
Under the No Action Alternative, the GMD ETR would not be established, and GBI and target launch scenarios would not be tested under operationally realistic conditions. All existing launch areas would continue their current operations. Transportation-related impacts from current operations have been evaluated in previous environmental documents, and no significant impacts were identified.

4.5.10.2 Alternative 1
Under the implementation of Alternative 1, target launches would occur from Vandenberg AFB.
4.5.10.2.1 Target Operation

Implementation of Alternative 1 would result in single and dual target launches from Vandenberg AFB. Target missile components would be built in contractor facilities and delivered to Vandenberg AFB via air or road for system assembly and checkout. Target missiles would not be shipped with initiators or other explosive devices. All missile components would be packaged in appropriately designed containers, labeled, and handled in accordance with applicable DOT regulations for the transport of hazardous materials. Some missile components may be shipped to a military airfield near the launch site and transferred to the launch site by vehicle. Trained personnel using only appropriately certified cranes and other materiel-handling equipment would handle missile components and handling equipment in accordance with approved SOPs. There would be as many as five target launches per year. Once at Vandenberg, the missile components would be stored in a Missile Assembly Building until they are assembled for launch.

A maximum of approximately 150 contractor, military, and government civilian personnel would be required to support a single target launch at Vandenberg AFB, whereas a dual target launch would require roughly 175 personnel. They would travel to Vandenberg AFB via commercial airliner or motor vehicle. Target missile contractor personnel would be housed in motels or hotels in the vicinity and would commute to the launch site daily. Government and military test personnel may use military or commercial lodging if available. Assuming 4 persons per vehicle, this would add approximately 40 to 45 vehicles, during peak hours, to the key local roads providing access to Vandenberg AFB such as SR-1, SR-135, Santa Lucia Canyon Road, SR-246, U.S. 101, and Central Avenue. Although the local road system would experience a slight increase in traffic, the increase would only minimally change the ADT on key local roads and would not result in an unacceptable Level of Service.

Target missile launches would not require the temporary closure of any roads off Vandenberg AFB. Roads near the launch pads on Vandenberg are all on U.S. Air Force property. Consequently, no off-base traffic would be affected. Thus, no adverse impact to the area’s transportation infrastructure is anticipated. Target missile launch activity would have no impact on air traffic in the immediate ROI but has the potential to affect rail traffic and marine traffic. However, at Vandenberg AFB, train movement through the base is monitored by electronic surveillance and radio communication between train engineers, station masters, and Vandenberg AFB launch personnel to minimize the possibility of a launch vehicle overflight (U.S. Army Space and Strategic Defense Command, 1994). This is done routinely at Vandenberg AFB, so the target missile launches would not represent a significant new impact. Similarly, ocean vessels would be notified in advance of launch activity by the appropriate safety office as part of their routine operations through a NOTAM by the 11th Coast Guard District. Again, since this is done on a regular basis already, impacts are expected to be not significant.

4.5.10.3 Alternative 2

Under the implementation of Alternative 2, GBI launches would be from Vandenberg AFB instead of KLC. The GBI would require construction of an IDT and possibly minor modifications of existing support facilities at Vandenberg AFB. Were any new communications cable/conduit required, they would be buried along existing roads, insofar as possible. The other components described in Alternative 1 would remain the same.
4.5.10.3.1 Ground-Based Interceptors

Construction
The modification of LF-21 and LF-23 to support GBI launches, and the modification of associated facilities to be used at Vandenberg AFB was analyzed in the Booster Verification EA and the Alternate Booster Vehicle EA and determined to cause no significant environmental impacts. The proposed action would include the use of up to two GBI silos. LF-21 and LF-23 could be used with very minor modifications. LF-02, LF-03, LF-10, and LF-24 would require varying levels of modification. Modifications would include those described in section 2.3.2.1.2. Additional facilities listed in table 2.3.2-1 would also require modifications. All construction staging areas would be located on paved or previously disturbed graded areas. Transportation impacts would be negligible.

For communication among the components at Vandenberg AFB, the proposed action would maximize use of available communications assets, to include cable. If communication cable is not available, new cable would be installed in new conduits. Cable routes would be designed to avoid environmental impacts and would be approved by 30 CES/CEV. Installation of cable would have a localized, minimal impact on transportation.

Operation
The impact from the launch of interceptor missiles would be similar to the impact from the launch of target missiles. Since existing transportation facilities at Vandenberg AFB would be utilized for the GMD ETR program, the presence of approximately 260 GMD program personnel during a single launch or 300 GMD program personnel during a dual launch test flight at Vandenberg AFB, would not adversely impact the transportation facilities at Vandenberg AFB.

4.5.10.3.2 In-Flight Interceptor Communication System Data Terminal

Construction
Implementation of Alternative 2 would result in the construction of an IDT on Vandenberg AFB. An all-weather road would be constructed as part of this alternative. Construction equipment, material, and personnel would arrive at Vandenberg AFB via air or road. Site preparation activities and construction of the IDT would have minimal impact on transportation.

Operation
An IDT site would normally be unmanned, except during acceptance/flight testing, preventative maintenance, corrective maintenance, and future upgrades; this could require support of up to ten personnel. When not in operation, the onsite, diesel-powered backup generators would be tested for approximately 200 hours per year.

Access to the IDT compound would be via an all-weather road from the nearest existing service road through a lockable service gate. There would be a similar road from the gate in the perimeter fence to the IDT building, and a patrol road circumnavigating the fence would be required. A hardened surface of 9.1 meters (30 feet), surrounding the concrete pad, would permit access for a crane or other required equipment where necessary. The personnel associated with the IDT would be a part of approximately 260 GMD program personnel required during a single launch or 300 GMD program personnel required during a dual GBI launch, and thus there would not be an additional impact to transportation systems.
4.5.10.4 Alternative 3
Alternative 3 would combine activities proposed for Alternatives 1 and 2 and would include GBI launches from both KLC and Vandenberg AFB and construction of the required support facilities. The impacts from construction of IDTs and minor modifications to existing facilities at Vandenberg AFB would be the same as the impacts described under Alternative 1 and Alternative 2. The impacts from single and dual GBI and single and dual target launches, as well as operation of range support equipment, would also be the same as described under Alternative 1 and Alternative 2.

4.5.10.5 Cumulative Impacts
Based on preliminary planning information for fiscal year 2002 through fiscal year 2007, the Proposed Action of up to five launches (interceptor and target), in conjunction with current planned or anticipated launches, would not exceed the current limit of 30 launches per year. Initial defensive operations capabilities being developed at Vandenberg AFB would not include missile launches. However, operations would include backup generators at four GBI LFs, and minor site preparation activities. The addition of the GMD ETR launches to the identified ongoing and future programs in the ROI would result in a minor cumulative impact on transportation.

4.5.10.6 Mitigation Measures
No transportation mitigation measures are proposed for the GMD ETR activities at Vandenberg AFB.

4.5.11 WATER RESOURCES—VANDENBERG AIR FORCE BASE

4.5.11.1 No Action Alternative
Existing operations would continue at Vandenberg AFB under the No Action Alternative and any new impacts associated with the GMD ETR would not occur. Water resources-related impacts from current operations have been evaluated in previous environmental documents, and no significant impacts were identified.

4.5.11.2 Alternative 1

4.5.11.2.1 Targets
Construction
Target missile-related construction activities at Vandenberg AFB under Alternative 1 would only consist of minor modifications to the interior of launch silos and associated support facilities. Therefore, there would not be any adverse construction-related water resource impacts under this alternative.

Operation
Deposition of rocket emission products onto surrounding surface waters would occur as a result of target missile launches; however, these impacts would not be significant. These types of impacts are further described in section 4.1.14.2.1. This same issue was assessed for
Vandenberg AFB rocket launches in each of the NEPA-related documents listed below. All of these studies reached the conclusion that related water quality impacts would be adverse but not significant.

- EA for Booster Verification Tests (U.S. Department of the Air Force, 1999)
- Final EIS Evolved Expendable Launch Vehicle (U.S. Department of the Air Force, 1998a)
- Theater Missile Defense Extended Test Range, Supplement to the Draft EIS (U.S. Army Space and Strategic Defense Command, 1994)

4.5.11.3 Alternative 2

4.5.11.3.1 Ground-Based Interceptors

The potential water resource impacts of GBI alternate booster verification construction activities at Vandenberg AFB were addressed by the Alternate Booster Vehicle Verification Test EA (U.S. Army Space and Missile Defense Command, 2002c). The Alternate Booster Vehicle EA concluded that potential impacts from construction and launches of these types of missiles would not be significant. Minor modifications to other support facilities would result in negligible impacts to water resources.

The proposed action would include the use of up to two GBI silos. LF-21 and LF-23 could be used with very minor modifications. LF-02, LF-03, LF-10, and LF-24 would require varying levels of modification. Modifications would include those described in section 2.3.2.1.2. Additional facilities listed in table 2.3.2-1 would also require modifications. All construction staging areas would be located on paved or previously disturbed graded areas. The GMD program would perform sampling and abatement for lead-based paint, asbestos, and polychlorinated biphenyls (PCBs) as required before modification, using Vandenberg AFB-approved procedures. Facility modifications and site preparation activities at the locations identified would have a negligible impact to water resources.

4.5.11.3.2 Targets

The target missile-related impacts associated with Alternative 2 would be the same as those described for Alternative 1 in section 4.5.10.2.1.

4.5.11.3.3 In-Flight Interceptor Communication System Data Terminal

Construction of an IDT under Alternative 2 would disturb approximately 5.9 hectares (14.6 acres) at Vandenberg AFB. Construction projects that disturb 1 acre or greater require a Construction Activities Storm Water General Permit from the California State Water Resources Control Board, or its local Central Coast Regional Water Quality Control Board. A related Stormwater Pollution Prevention Plan would also need to be prepared before the commencement of any soil-disturbing activities. All appropriate water quality-related Best Management Practices would be followed during construction, and related water quality impacts would not be significant. Operation of the IDT would not cause water quality impacts and potable water supplies are sufficient to handle the minor increase in potable water demand.
4.5.11.4  Alternative 3

Alternative 3 would require minor modifications to existing GBI launch sites, and the use of existing missile support facilities and radars. These types of impacts are described under Alternatives 1 and 2.

4.5.11.5  Cumulative Impacts

The major cumulative water resource impact in the Vandenberg AFB ROI is an overdraft condition in the Lompoc Terrace aquifer, caused by the groundwater pumping of a number of communities and water users, including Lompoc and Vandenberg AFB. As Vandenberg AFB continues to rely on imported surface water from the California Department of Water Resource’s State Water Project, Vandenberg AFB’s contribution to this cumulative impact would continue to diminish over time and overdraft conditions in the aquifer should improve.

Cumulative, but minor and temporary, increases in stormwater runoff and related discharges of sediments have also occurred in base drainages. These insignificant impacts have typically occurred near areas that have been paved during past construction projects and where runoff rates have increased. Such impacts have been and would continue to be minimized by construction SOPs and the other commitments included in the related Stormwater Pollution Prevention Plans.

Initial defensive operations capabilities being developed at Vandenberg AFB would not include missile launches. However, operations would include backup generators at four GBI LFs, and minor site preparation activities. The operation of backup generators at each LF would be similar to those described above for the IDT, and would result in no cumulative impacts to water resources.

The proposed action of up to five missile launches per year, in combination with other planned launches and activities, would not result in cumulative impacts to surface water, ground water, or ocean water quality.

4.5.11.6  Mitigation

No water resources mitigation measures are proposed for the GMD ETR activities at Vandenberg AFB.
4.6 PEARL HARBOR—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE

4.6.1 AIR QUALITY—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PEARL HARBOR

4.6.1.1 No Action Alternative

Under the No Action Alternative, the GMD ETR would not be established, and interceptor and target launch scenarios would not require the SBX for testing under operationally realistic conditions. Current air emission levels would remain the same, as listed in table 4.6.1-1. Operations currently conducted at Pearl Harbor would continue.

4.6.1.2 Alternatives 1, 2, and 3

Construction

Construction and facility modification required to provide support to the SBX would occur in previously disturbed areas. Construction activities would be conducted in accordance with all appropriate regulations and permits. Other than minor, short-term impacts from construction, no exceedances of the NAAQS or state AAQS would be anticipated.

Operation

If the SBX were to use Pearl Harbor as a PSB, the current plan would be to moor the SBX off of Barbers Point as shown in figure 2.3.1-13. If an alternate mooring location is identified for Pearl Harbor, additional siting studies would be performed. Air quality impacts at an alternate location off of Oahu are expected to be similar to those described below for the Barbers Point location, and would be verified prior to SBX operation.
Operational emissions aboard the SBX would be limited to the exhaust produced by generators and maintenance. Maintenance-related emissions would include minimal levels of volatile organic compound emissions that are not expected to have a significant impact on air quality.

65 Percent and Fully Populated SBX
Based on five tests per year the SBX would be at the Pearl Harbor PSB for 7 months. For conservative analysis purposes, 9 months will be used. The SBX is being analyzed as a mobile source with an expected use of 6,600 hours per year (24 hours a day for 9 months) at a single location, approximately 4.8 kilometers (3 miles) from Barbers Point. The SBX on-board power plant planned for use would include eight 3.64-MW diesel driven generators. While at the Barbers Point mooring site, only three of the generators would be used. One would operate continually while at the mooring location for daily ship functions. The other two generators would be required for powering of the 65 percent or fully populated radar for 3 hours per day. This represents 6,600 hours of operation of one 3.64-MW generator and 1,650 hours (825 hours each) of operation for the other two generators that would be in operation at the PSB. Total power output for the three 3.64-MW generators would be 30,030 MW hours for the time the SBX is at the PSB. The SBX would not be considered a stationary source at Pearl Harbor; therefore neither a Prevention of Significant Deterioration review nor a Title V permit would be required.

The remaining 3 months of the year it is expected the SBX would be in transit or at one of the SBX operating areas in the BOA.

4.6.1.3 Cumulative Impacts
No other projects in the ROI have been identified that would have the potential for incremental, additive cumulative impacts to the air quality in the ROI.

4.6.1.4 Mitigation Measures
No air quality resources mitigation measures are proposed for GMD ETR activities.

4.6.2 AIRSPACE—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PEARL HARBOR

4.6.2.1 No Action Alternative
Under the No Action Alternative, the GMD ETR would not be established and interceptor and target launch scenarios would not require the SBX for testing under operationally realistic conditions. Operations currently conducted at Pearl Harbor would continue.

4.6.2.2 Alternatives 1, 2, and 3
The Proposed Action related to airspace would be full power emissions from the SBX while at the mooring location south of Barbers Point. If an alternate mooring location is identified for Pearl Harbor, additional siting studies would be performed. Airspace impacts at an alternate location off of Oahu are expected to be similar to those described below for the Barbers Point location, and would be verified prior to SBX operation. A location outside the approach/departure area for Honolulu International Airport would probably reduce the potential restrictions on SBX operations and simplify the coordination process.
Operation

Controlled and Uncontrolled Airspace

Unrestricted operation of the SBX at the mooring location would have the potential to adversely affect aircraft operations. As discussed in section 4.3.2.2.1, the SBX would not exceed military aircraft interference standards or the FAA standard for peak power levels. The SBX could exceed the 300 V/m average power threshold. The average power threshold is based upon reducing the time of exposure of aircraft avionics (electronic equipment) to High Intensity Radiated Fields in order to preclude shortening the life of the aircraft avionics. Therefore, the concern is not interference but is a reduction in life of the aircraft avionics. As shown in table 2.1.4-2, the fully populated radar has a potential for interference with aircraft (exceeding the 300 V/m average power threshold) out to a distance of 19 kilometers (11.8 miles) from the SBX.

In order to avoid or minimize adverse effects from EMR/EMI, DoD has established a coordination process with responsible agencies and airspace users. A full EMR/EMI survey and analysis would be conducted by the Joint Spectrum Center, in coordination with the FAA, DOT, and other potentially affected users. The survey is used in preparing a DD Form 1494 that would be required as part of the spectrum certification and frequency allocation process. The completed DD Form 1494 that has been processed and approved by the appropriate national and international authorities would be required prior to SBX testing.

The results of the survey would also be used to define the operating area for the SBX (acceptable azimuths and operating angles). The maximum operating area would be all azimuths (360 degrees), and all angles up to 90 degrees. The maximum potential interference distances are listed in table 2.1.4-2 and are shown on figure 3.6.2-1.

The actual SBX operating area at the mooring location would be restricted in order to minimize impacts to aircraft operations, EEDs, and communication equipment. A high energy radiation area notice would be published on the appropriate aeronautical charts, notifying aircraft of a radio frequency radiation area. The boundaries of the SBX high energy radiation area would be configured to minimize impacts to aircraft operations, EEDs, and communications equipment. The establishment of this SBX high energy radiation area would not impose any new flight restriction requirements.

SBX operations would be coordinated with the FAA and would be scheduled to occur during hours of minimal aircraft operations. In addition, the SBX would utilize a real-time link to the FAA operations radar to insure the airspace is clear of any aircraft prior to operating the SBX. Consequently, there would be no reduction in the amount of navigable airspace, and thus no impacts to the controlled and uncontrolled airspace in the ROI would result.

Special Use Airspace

There is no special use airspace within the ROI. Consequently, there would be no impacts to special use airspace.

En Route Airways and Jet Routes

Several en route low altitude airways (V15, V12, V4, V16, V8, V2, V20, and V21) cross the 65 percent and fully populated aircraft interference areas. There are additional approach and departure routes within the ROI that would also need to be considered when defining the SBX.
The SBX would be programmed to limit RF emissions in the direction of airways that pass within the potential interference distance. In addition, since the radar beam is in constant motion, should an aircraft enter the interference area, it is highly unlikely that the SBX would illuminate an aircraft long enough to affect the on-board electronics.

**Airports and Airfields**
Honolulu International Airport is located approximately 19 kilometers (11.8 miles) east of the SBX mooring. Kalaeloa (Rodgers) Airport is located approximately 7 kilometers (4.3 miles) northeast of the mooring site, and Wheeler Army Airfield is located several kilometers (several miles) northeast of the ROI. Traffic control radars at these locations would be major factors in the EMR/EMI survey and analysis and subsequent operating permit. Operation of the SBX has the potential to interfere with both aircraft systems and air navigation systems. However, the SBX high-energy radiation area would be configured not to impose any flight restriction requirements and would not change any airfield/airport arrival and departure traffic flows.

There are a number of air navigation facilities within the airspace ROI. However, they operate at lower frequencies (in the mHz range) than the X-band SBX and would not normally experience any interference from the SBX. Nevertheless, there is the potential for interference from the grating (side) lobes and the main beam. Section 4.6.5 (Health and Safety) provides a detailed discussion of the potential for electronic communications (in-band and adjacent band) and harmonic band RF interference, as well as non-frequency-related interference (high power effects).

Emissions from the SBX may also potentially degrade the overall system performance of in-band airborne and ship based systems such as fire control, bomb/navigation in military aircraft, and weather radars in both civilian and military aircraft, which all operate in the X-band (8 to 12 GHz). However, the SBX high energy radiation area would be configured to minimize impacts to these airborne and ship based systems.

**4.6.2.3 Cumulative Impacts**
Because the SBX operates in different frequency ranges than most aircraft radars, there would be limited potential for an incremental, additive cumulative electromagnetic effect upon the operation of an air navigation facility or the signal used by aircraft. Moreover, the frequency allocation operating permit process would take into consideration potential impacts on other resources in the region and would preclude the potential for cumulative impacts.

No other projects in the airspace ROI have been identified that would have the potential for other incremental, additive cumulative impacts to controlled or uncontrolled airspace, special use airspace, en route airways and jet routes, or airfields and airports.

**4.6.2.4 Mitigation Measures**
The SBX high-energy radiation area would be configured to mitigate potential impacts to aircraft and other potentially affected systems, and would be published on aeronautical charts. In addition to charting the SBX high energy radiation area notice, information would be published in the Airport Facility section of the FAA Airport Guide, and local NOTAMs would be issued. Additionally, flight service personnel would brief pilots flying in the vicinity about the SBX high energy radiation area.
4.6.3 BIOLOGICAL RESOURCES—SEA-BASED TEST X-BAND RADAR
PRIMARY SUPPORT BASE, PEARL HARBOR

4.6.3.1 No Action Alternative

Under the No Action Alternative, the GMD ETR would not be established and interceptor and target launch scenarios would not require the SBX for testing under operationally realistic conditions. Operations currently conducted at Pearl Harbor would continue.

4.6.3.2 Alternatives 1, 2, and 3

Section 2.1.4 includes a description of the SBX.

Construction

Any construction or facility modification required to provide support to the SBX would occur in previously disturbed areas in accordance with host installation guidelines and regulations. Other than minor, short-term impacts from noise, such as startling and temporary displacement, no adverse effects to biological resources are anticipated.

Operation

If the SBX were to use Pearl Harbor as a PSB, the current plan would be to moor the SBX off of Barbers Point as shown in figure 2.3.1-13. If an alternate mooring location is identified for Pearl Harbor, additional siting studies would be performed. Biological impacts at an alternate location off of Oahu are expected to be similar to those described below for the Barbers Point location, and would be verified prior to SBX operation.

Section 4.3.3.3 includes a general description of the potential for impacts from operation of the SBX. As described in section 2.1.4, the SBX would be mounted on a semi-submersible sea platform. The sea platform would be self-propelled in open water with a cruising speed of approximately 15 kilometers per hour (8 knots), but towed while in port. Total height of the SBX above the water line including the XBR radome would be approximately 76.3 meters (250 feet) at transit draft. The SBX main beam would not be directed toward the ground or water surface and would have a lower limit of 10 degrees above horizontal for calibration and maintenance testing while at the Primary Support Base. The transmit/receive RF emission pattern would be mostly contained within a narrow main beam. The total amount of RF radiation per week would be approximately 5 to 6 hours. A full EMR/EMI survey and analysis would be conducted by the Joint Spectrum Center, in coordination with the FAA, DOT, and other potentially affected users. An operating permit would be negotiated based on the results of the EMR/EMI survey.

The radar main beam would not be directed toward the ground, which, when combined with the height of the SBX, limits the probability of energy absorption by surface-oriented wildlife. The main beam would normally be in motion, making it extremely unlikely that a bird would remain within the most intense area of the beam for any considerable length of time. The size of the beam is relatively small, which further reduces the probability of bird species remaining within this limited region of space, even if the beam were still. (Ballistic Missile Defense Organization, 2000)

Analyses based on the conservative assumption that the energy absorption rate of a bird’s body was equal to its resting metabolic rate and that this may pose a potential for an adverse effect
determined that birds are not likely to remain continuously within the radar beam, and the power density is not expected to exceed levels stated above that could impact birds; thus, the likelihood of harmful exposure is not great. (Ballistic Missile Defense Organization, 2000)

Humpback whales forage and calve during the winter months beyond the 183-meter (600-foot) depth contour. As stated earlier, the SBX main beam would not be directed toward the surface of the ocean, and marine mammals would normally be found below the surface of the water. The power density level just below the surface of the ocean would not exceed the permissible exposure level for uncontrolled environments. (U.S. Department of the Navy, 2002a) No adverse impacts would occur to whales, other marine mammals, or sea turtles at least 1.3 centimeters (0.5 inch) below the surface. It is also highly unlikely that an individual would be on or substantially above the surface of the water for a significant amount of time within the main beam or side lobe areas when the SBX would be operating. For these reasons, no effects are anticipated on the humpback whale, other marine mammals, or sea turtles that might be present in the vicinity of the homeport and transit locations. Operation of the SBX would not require delays if humpback whales and other marine mammals are observed. Therefore, no further action regarding humpback whales is required pursuant to the Endangered Species Act and the Marine Mammal Protection Act.

The SBX vessel would incorporate marine pollution control devices such as keeping decks clear of debris, cleaning spills and residues, and engaging in spill and pollution prevention practices in compliance with the UNDS provisions of the Clean Water Act. The potential for impacts to marine mammals or sea turtles due to an accidental release of diesel fuel is considered low. It is unlikely that the Hawaiian monk seal would be present at the offshore location of the SBX platform. There is evidence that dolphins can identify the presence of diesel fuel and lubricating oil and avoid it (U.S. Department of the Navy, 2001). The relatively slow speed of the SBX platform would preclude the potential for collision with a free-swimming marine mammal. Overall, no adverse impacts to marine mammals are anticipated.

4.6.3.3 Cumulative Impacts

No other projects in the ROI have been identified that would have the potential for incremental, additive cumulative impacts to biological resources in the ROI. As stated above, no effects are anticipated on the humpback whale, other marine mammals, or sea turtles that might be present in the vicinity of the homeport and transit locations.

4.6.3.4 Mitigation Measures

No biological resources mitigation measures are proposed for GMD ETR activities.

4.6.4 HAZARDOUS MATERIALS AND HAZARDOUS WASTE—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PEARL HARBOR

4.6.4.1 No Action Alternative

Under the No Action Alternative, the GMD ETR would not be established and interceptor and target launch scenarios would not require the SBX for testing under operationally realistic conditions. Operations currently conducted at Pearl Harbor would continue.
4.6.4.2 Alternatives 1, 2, and 3

Construction

Any construction or facility modification required to provide support to the SBX would occur in previously disturbed areas in accordance with host installation guidelines and regulations. Other than minor, short-term increase from the use of potentially hazardous materials such as paints, solvents and fuels, no adverse effects to ongoing hazardous materials storage and handling are anticipated. The small increases in the amount of potentially hazardous materials used during construction activities would result in generation of added wastes. However, this increase is not expected to be significant and would be accommodated in accordance with existing protocol and regulations.

Operation

If the SBX were to use Pearl Harbor as a PSB, the current plan would be to moor the SBX off of Barbers Point as shown in figure 2.3.1-13. If an alternate mooring location is identified for Pearl Harbor, additional siting studies would be performed. Hazardous materials and hazardous waste impacts at an alternate location off of Oahu are expected to be similar to those described below for the Barbers Point location, and would be verified prior to SBX operation.

Shipboard Hazardous Materials and Waste Management

The Navy requires that, to the maximum extent practicable, ships shall retain hazardous waste aboard ship for shore disposal. If hazardous materials are discharged overboard, this must occur more than 370 kilometers (200 nautical miles) from land. Discharging hazardous materials overboard is not standard practice and would only be done as a worst case scenario.

Twenty-five liquid discharges, such as clean ballast, deck runoff and dirty ballast, from the normal operation of Armed Forces vessels are required to be controlled by installation of control technologies or use of management practices (marine pollution control devices) under the UNDS provisions of the Clean Water Act. In compliance with UNDS, the SBX vessel would incorporate marine pollution control devices, such as keeping decks clear of debris, cleaning spills and residues and engaging in spill and pollution prevention practices, in design or routine operation.

Increased operations that could take place on Pearl Harbor would be servicing and maintenance of the SBX. The supply barge that would service the SBX vessel would transport potentially hazardous materials and hazardous waste from the SBX to the pier at Pearl Harbor. The quantity of hazardous materials and hazardous waste is not expected to significantly affect the PSB generator status or significantly affect current hazardous materials management or waste disposal practices. There would be no significant operational impacts, and no mitigation would be required.

4.6.4.3 Cumulative Impacts

No other projects in the ROI have been identified that would have the potential for incremental, additive cumulative impacts to existing hazardous materials and waste management practices.

4.6.4.4 Mitigation Measures

No hazardous materials/waste management mitigation measures are proposed.
4.6.5 HEALTH AND SAFETY—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PEARL HARBOR

4.6.5.1 No Action Alternative

Under the No Action Alternative, the primary support base for the SBX would not be located at Pearl Harbor/Barbers Point. Operations currently conducted at Pearl Harbor would continue.

4.6.5.2 Alternatives 1, 2, and 3

Construction

Any construction or facility modification required to support the SBX would occur in accordance with existing host installation safety protocol/plans and applicable state and federal requirements. Public access to Pier Victor 3 would be limited. No adverse effects to health and safety of construction contractors or the public are anticipated.

Operations

If the SBX were to use Pearl Harbor as a PSB, the current plan would be to moor the SBX off of Barbers Point as shown in figure 2.3.1-13. If an alternate mooring location is identified for Pearl Harbor, additional siting studies would be performed. Health and safety impacts at an alternate location off of Oahu are expected to be similar to those described below for the Barbers Point location, and would be verified before SBX operation.

Configuration and general operation of the SBX would occur as described in section 2.1.4. The transmit/receive RF emission pattern would be mostly contained within a narrow main beam. The total duration of RF radiation per week would be approximately 5 to 6 hours.

An EMR/EMI survey and analysis would be conducted by the Joint Spectrum Center that considers HERP, HERF, and HERO. The survey is used in preparing a DD Form 1494 that would be required as part of the spectrum certification and frequency allocation process. The completed DD Form 1494 that has been processed and approved by the appropriate national and international authorities would be required prior to SBX testing.

The analysis provides recommendations for sector blanking and safety systems to minimize exposures. The proposed systems would have the appropriate safety exclusion zones established before operation, and warning lights to inform personnel when the system is in operation and emitting EMR. Mechanical and software stops would be used to prevent the main beam from being directed in specified sectors where it may present a hazard.

Potential health and safety impacts related to human exposure, EEDs, fuels, communications—electronics interference, and aircraft avionics would be similar to those described in section 4.3.5.2.5. Appendix G also provides summary information regarding potential SBX EMR issues.

The actual operating area of the SBX at the mooring location would be restricted to minimize impacts. SBX operations would be coordinated with the FAA, Coast Guard and other groups or agencies as appropriate. Therefore, no health and safety impacts to coastal areas, airspace/aircraft, or mariners are anticipated.
4.6.5.3 Cumulative Impacts

The concept of time averaging is important in consideration of the potential cumulative exposures that might occur near operating radars. Because tracking and search radar beams move rapidly, depending on the particular mission or exercise, it is unlikely that environmental exposures would ever consist of continuous, constant values of power density. Rather, almost universally, exposures would be intermittent and, when the radars are transmitting, the electromagnetic fields would be constantly changing in intensity. Thus, the potential for additive, incremental cumulative impacts from EMR exposure is extremely limited.

4.6.5.4 Mitigations

Limitations imposed on the range of azimuth and angles of operation would preclude potential impacts related to health and safety. Mechanical and software stops would be used to control the radar’s operation.

4.6.6 UTILITIES—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PEARL HARBOR

This section addresses potential environmental impacts caused by changes to the utilities services due to the proposed construction and operation of the SBX element. Potential impacts considered include potential effects from ongoing or planned activities at these sites.

4.6.6.1 No Action Alternative

Under the No Action Alternative, the GMD ETR would not be established, and the SBX would not be developed to support interceptor and target launch scenarios, needed for operationally realistic test conditions. Pearl Harbor would continue their current operations.

4.6.6.2 Alternatives 1, 2, and 3

If the SBX were to use Pearl Harbor as a PSB, the current plan would be to moor the SBX off of Barbers Point as shown in figure 2.3.1-13. If an alternate mooring location is identified for Pearl Harbor, additional siting studies would be performed. Utilities impacts at an alternate location off of Oahu are expected to be similar to those described below for the Barbers Point location, and would be verified prior to SBX operation.

Electrical power requirements for the SBX platform and its various payloads would be approximately 21.84 MW, supplied by six on-board 3.64-MW generators. The SBX would be self-propelled by two of four steerable 3.4-MW electric thrusters that would effectively drive and maneuver the SBX without assistance. During transportation, these retractable, Z-drive thrusters would consume approximately 7 MW, leaving 14.8 MW available for necessary shipboard operations, as well as the XBR.

The SBX has a fuel capacity of approximately 3,100,000 liters (818,000 gallons). The approximate fuel consumption for transit and radar operation is 54,800 liters (14,500 gallons) per day, which would only amount to approximately 1.8 percent of total fuel capacity daily. Fuel consumption at the mooring site would be approximately 11,350 liters (3,000 gallons) per day.
There would be a total of 50 crew members, including 20 marine crew and 30 GMD mission support personnel. Additionally, up to 50 people could be accommodated on board on a temporary daytime basis.

At the intervals between GMD test missions, the SBX would typically return to a PSB, or an adjacent mooring station, for crew rotations, re-supply, and maintenance activities. If at the adjacent mooring location, three of the six generators would still be used, one operating continually while in port for daily ship functions while the remainder would power the half- or fully populated radar 3 hours per day.

When the SBX is at the Barbers Point mooring site, about 4.8 kilometers (3 miles) off Barbers Point (figure 2.3.1-13), a supply ship would deliver supplies, repair parts, and fuel. The most likely area to dock the supply ship would be at Pier Victor 3. Personnel would be ferried to the SBX each day either by watercraft or helicopter. There would be no direct impacts to area utilities from the self-contained SBX.

A utility hookup would be required for the supply ship to run onboard lighting and other basic needs. Supply ships would utilize Pier Victor 3. The pier is currently supplied with a 15-centimeter (6-inch) potable water line (Noborikawa, 2002) and jet fuel, and although there are no shore power dock outlets, power lines run near enough to allow relatively easy modification to provide the platform with primary shore power. Electricity requirements are typically supplied by power lines linking to nearby buildings; as an option, a temporary transformer, tapped into a primary line, can be provided (Noborikawa, 2002). Due to the possibility of cross-contamination, regulations prevent the Public Works Center from providing a wastewater line at Pier Victor 3 (Noborikawa, 2002), and wastewater, as well as solid waste, would have to be containerized and arrangements made with local authorities on an as-needed basis to provide for their disposal.

Should existing facilities at Pearl Harbor be unavailable or inadequate at the PSB to accommodate approximately 25 personnel, construction of new storage and administration facilities would be necessary. If existing facilities were used, security upgrades, environmental controls for storage areas, fueling capability, ship gases handling facilities, computer networks, phone systems, and hazardous material storage and disposal may be added. Ongoing logistics and support operations such as re-supply, fueling and maintenance and crew/operator training would also occur at the PSB. Warehouses in the same fenced compound as Pier Victor 3 would possibly be renovated for SBX use, or new warehouses and administrative facilities could be constructed.

Studies have shown an average 189 liters (50 gallons) per capita per day water consumption and 170 liters (45 gallons) per capita per day of wastewater production. Recent figures indicate that in the United States, the per capita generation of municipal solid waste in 1998 was 2 kilograms (4.46 pounds) per capita per day (U.S. Environmental Protection Agency, Region 9, 2002). Average daily demand for water, wastewater, and municipal solid waste for a maximum 25 personnel would be estimated as follows, based on typical usage: 4,725 liters (1,250 gallons) water; 4,258 liters (1,125 gallons) wastewater and 50 kilograms (112 pounds) of solid waste. Any new facilities being constructed would be required to facilitate this level of use, as well as to accommodate any energy demand.
4.6.6.3 Cumulative Impacts

At this time, there are no ongoing or foreseeable future programs/plans identified in the ROI that, when combined with the relatively minor SBX utility requirements, would result in cumulative impacts to utilities. Therefore, no cumulative impacts are anticipated with Alternatives 1, 2, and 3.

4.6.6.4 Mitigation Measures

No utilities mitigation measures are proposed for the GMD ETR activities.

4.6.7 VISUAL AND AESTHETIC RESOURCES—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PEARL HARBOR

4.6.7.1 No Action Alternative

Under the No Action Alternative, the SBX would not be located off-shore at Barbers Point. There would be no alteration of the existing visual setting and the adjacent area. The SBX facilities at Pearl Harbor would be visually synonymous with historic and present military activities that occur there. The SBX would have a very minor impact on views from Barber's Point. No significant impacts to visual and aesthetic resources would occur.

4.6.7.2 Alternatives 1, 2, and 3

In an effort to determine the existing visual quality of each of the SBX locations, the following method was modified from "Landscape Aesthetics: A Handbook for Scenery Management" (U.S. Department of Agriculture, U.S. Forest Service, 1995). The handbook outlines ways to measure individual aspects of visual resources and then rate the scenic value class of each of the locations. The following criteria were used to determine the scenic value class for the potential SBX locations: scenic attractiveness, viewer concern, and distance zones. Scenic attractiveness is the measure of scenic quality based on human perceptions of inherent beauty of the forms, colors, textures, and visual composition of an individual landscape. Viewer concern can be defined as the level of scenic importance based on expressed human concern for the scenic quality of land areas viewed. The distance zone is a principal indicator of scenic importance based on the distance an area can be seen by observers, and the degree of visible detail within that zone. In addition, scenic integrity is included to determine the current level of modification to an area. A description of the scenic value rating criteria and scenic attractiveness can be found in appendix B.

Scenic Attractiveness

Several areas such as residential areas, resort locations, and recreational areas at Barbers Point where the SBX would be visible can be classified as having a “Distinctive” (A) scenic attractiveness because of the unique visual quality and the strong positive attributes.

Concern Level

The concern level of the viewers at Barbers Point would be considered to be “high” (Level 1) due to the recreational and residential use of the adjacent and surrounding areas.
Distance Zone
The mooring area would be approximately 5 kilometers (3 miles) away from shore, which is the mid-ground (MG), but could potentially be viewed in the foreground (FG) by recreational boaters and fishermen.

Scenic Value Class
The scenic value class for Pearl Harbor as determined from the scenic value class table, table 4.6.7-1, is 1, which equates to a high public value.

Scenic Integrity
The SBX mooring site has a very high scenic integrity level, which is defined as a landscape where the valued landscape is intact with only insignificant if any deviation or disturbance. This would contribute to the area’s high scenic value.

Visual resources would be slightly affected by the proposed SBX off-shore at Barbers Point. The radar would be approximately 5 kilometers (3 miles) away from the beach and approximately 76 meters (250 feet) tall. These figures would account for a 1-degree line-of-sight with the horizon for the SBX if the viewer were standing on the shore. This measurement would be comparable to boats and ships passing along the horizon. The SBX would be moored at an adequate distance away from the shore and would not obstruct panoramic views.

Visual resources could also be affected by the SBX if it is in the line-of-sight from boats to the island. However, the SBX would only inhibit the view of the island temporarily, as the boat passes by.

1-2: High public value.
3-5: Moderate public value.
6-7: Low public value.
4.6.7.3 Cumulative Impacts
The SBX would be at the mooring location intermittently throughout the year. No other activities have been identified that would contribute to cumulative impacts.

4.6.7.4 Mitigation Measures
No visual resources mitigation measures are proposed for the GMD ETR activities.
4.7 NBVC PORT HUENEME—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE

4.7.1 AIR QUALITY—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, NBVC PORT HUENEME

4.7.1.1 No Action Alternative

Under the No Action Alternative, the GMD ETR would not be established and interceptor and target launch scenarios would not require the SBX for testing under operationally realistic conditions. Operations currently conducted at NBVC Port Hueneme/San Nicolas would continue. Table 4.7.1-1 lists the existing emissions at San Nicolas Island.

4.7.1.2 Alternatives 1, 2, and 3

Construction

Warehouse and administrative space may be available at NBVC Port Hueneme. If required, construction and facility modification to provide the needed space would occur in previously disturbed areas. All construction activities would be conducted in accordance with appropriate regulations and permits. Other than minor, short-term impacts from construction, no adverse effects to regional air quality are expected.

Operation

Operational emissions aboard the SBX would be limited to the exhaust produced by generators and maintenance. Maintenance-related emissions would include minimal levels of volatile organic compound emissions that are not expected to have a significant impact on air quality.

65 Percent and Fully Populated SBX

Based on five tests per year the SBX would be at the NBVC Port Hueneme PSB for 7 months. For conservative analysis purposes, 9 months will be used. The SBX is being analyzed as a mobile source with an expected use of 6,600 hours per year (24 hours a day for 9 months) at a single location, approximately 1.6 kilometers (1 mile) east of San Nicolas Island. The SBX on-board power plant planned for use would include eight 3.64-MW diesel driven generators. While at the mooring location at San Nicolas Island, only three of the generators would be used. One would operate continually while in port for daily ship functions. The other two generators would be required for powering of the 65 percent or fully populated radar for 3 hours per day. This represents 6,600 hours of operation of one 3.64-MW generator and 1,650 hours (825 hours each) of operation for the other two generators that would be in operation at the PSB. Total power output for the three 3.64-MW generators would be 30,030 MW hours for the time the SBX is at the PSB. The SBX would not be considered a stationary source at San Nicolas Island; therefore neither a Prevention of Significant Deterioration review nor a Title V permit would be required.
The remaining 3 months of the year it is expected the SBX would be in transit or at one of the SBX operating areas.

Under the provisions of the 40 CFR Parts 51 and 93, federal actions are required to be in conformity with the State Implementation Plan for those areas categorized as nonattainment or maintenance areas for an criteria pollutant. While San Nicolas Island is within Ventura County, which is in nonattainment for federal and state ozone levels and state PM-10 levels, San Nicolas' regional air quality is considered to be in attainment or unclassifiable. The provisions of the General Conformity Rule do not apply to activities occurring at San Nicolas Island. (Department of the Navy, Naval Air Warfare Center, Weapons Division, 2002)

4.7.1.3 Cumulative Impacts
No other projects in the ROI have been identified that would have the potential for incremental, additive cumulative impacts to regional air quality in the ROI.

4.7.1.4 Mitigation Measures
No air quality mitigation measures are proposed for GMD ETR activities.

4.7.2 AIRSPACE—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PORT HUENEME
4.7.2.1 No Action Alternative
Under the No Action Alternative, the GMD ETR would not be established, and interceptor and target launch scenarios would not require the SBX for testing under operationally realistic conditions. Operations currently conducted at NBVC Port Hueneme and San Nicolas Island would continue.

4.7.2.2 Alternatives 1, 2, and 3
The Proposed Action related to airspace would be full power emissions from the SBX while at the mooring location southeast of San Nicolas Island.

Operation
Controlled and Uncontrolled Airspace
Unrestricted operation of the SBX at the mooring location would have the potential to adversely affect air operations. As discussed in section 4.3.2.2.1, the SBX would not exceed military aircraft interference standards or the FAA standard for peak power levels. The SBX could exceed the 300 V/m average power threshold. The average power threshold is based upon reducing the time of exposure of aircraft avionics (electronic equipment) to High Intensity Radiated Fields in order to preclude shortening the life of the aircraft avionics. Therefore, the concern is not interference but is a reduction in life of the aircraft avionics. As shown in table 2.1.4-2, the fully populated radar has a potential for interference with aircraft (exceeding the 300 V/m average power threshold) out to a distance of 19 kilometers (11.8 miles) from the SBX.

To avoid or minimize adverse effects from EMR/EMI, DoD has established a coordination process with responsible agencies and airspace users. A full EMR/EMI survey and analysis would be conducted by the Joint Spectrum Center, in coordination with the FAA, DOT, and
other potentially affected users. The survey is used in preparing a DD Form 1494 that would be required as part of the spectrum certification and frequency allocation process. The completed DD Form 1494 that has been processed and approved by the appropriate national and international authorities would be required prior to SBX testing.

The results of the survey would also be used to define the operating area for the SBX (acceptable azimuths and operating angles). The maximum operating area would be all azimuths (360 degrees), and all angles up to 90 degrees. The maximum potential interference distances are listed in table 2.1.4-2 and are shown on figure 3.7.2-1.

The actual SBX operating area at the mooring location would be restricted in order to minimize impacts to aircraft operations, EEDs, and communication equipment. A high energy radiation area notice would be published on the appropriate aeronautical charts, notifying aircraft of a RF radiation area. The boundaries of the SBX high energy radiation area would be configured to minimize impacts to aircraft operations and other potentially affected systems. The operating area would be similar to the existing operating area for the GBR-P radar at Kwajalein (figure 4.3.2-1).

SBX operations would be coordinated with the FAA and NAWCWD and would be scheduled to occur during hours of minimal aircraft operations if possible. Consequently, there would be no reduction in the amount of navigable airspace, and thus no impacts to the controlled and uncontrolled airspace in the ROI would result.

**Special Use Airspace**

The airspace over San Nicolas Island is within the Point Mugu Sea Range and is located within Warning Area W-289. This Warning Area is active on an intermittent basis and is activated in coordination with the FAA. Notification is made through NOTAMs issued by the FAA. There is also a restricted airspace R222 located above San Nicolas Island and extending outward approximately 6 kilometers (3.7 miles). The SBX high-energy radiation area would be partially contained within this restricted area and wholly contained within Warning Area W-289. Coordination between the FAA, NAWCWD, and the SBX would mitigate potential conflicts between users of the special use airspace. Consequently, there would be no impacts to special use airspace.

**En Route Airways and Jet Routes**

En route airways that cross the Point Mugu Sea Range north and south of the proposed mooring area are within special CAE airways. Neither CAE is within the ROI; therefore, impacts to the en route airways are not anticipated.

**Airports and Airfields**

The SBX would be programmed to limit RF emissions in the direction of airways that pass within the potential interference distance. In addition, since the radar beam is in constant motion, it is highly unlikely that the SBX would illuminate an aircraft long enough to affect the on-board electronics. There is one runway on San Nicolas Island. Other runways in the region are located more than 97 kilometers (60 miles) from the mooring location. With the controls placed on the SBX in a manner similar to the GBR-P radar, standard instrument approach and departure procedures at the San Nicolas Island would continue unhindered. Existing airfield arrival and departure traffic flows would also not be affected, and access to the airfield would
not be curtailed. All arriving and departing aircraft and all participating military aircraft are under the control of the military tower at NAS Point Mugu; thus, there would be no airfield conflicts in the ROI under the Proposed Action, and no impact.

4.7.2.3 Cumulative Impacts
Because the SBX operates in different frequency ranges than most aircraft radars, there would be limited potential for an incremental, additive cumulative electromagnetic effect upon the operation of an air navigation facility or the signal used by aircraft. The use of the required scheduling and coordination process, and adherence to applicable DoD directives and regulations concerning radar operations would preclude the potential for significant incremental, additive, cumulative impacts.

No other projects in the airspace ROI have been identified that would have the potential for other incremental, additive cumulative impacts to controlled or uncontrolled airspace, special use airspace, en route airways and jet routes, or airfields and airports in the ROI.

4.7.2.4 Mitigation Measures
The SBX high energy radiation area would be configured to mitigate potential impacts to aircraft and other potentially affected systems, and would be published on aeronautical charts. In addition to charting the SBX high energy radiation area notice, information would be published in the Airport Facility section of the FAA Airport Guide, and local NOTAMs would be issued. Additionally, flight service personnel would brief pilots flying in the vicinity about the SBX high energy radiation area.

4.7.3 BIOLOGICAL RESOURCES—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PORT HUENEME

4.7.3.1 No Action Alternative
Under the No Action Alternative, the GMD ETR would not be established and interceptor and target launch scenarios would not require the SBX for testing under operationally realistic conditions. Operations currently conducted at NBVC Port Hueneme/San Nicolas would continue.

4.7.3.2 Alternatives 1, 2, and 3

Construction
Any construction or facility modification required to provide support to the SBX would occur in previously disturbed areas in accordance with host installation guidelines and regulations. Other than minor, short-term impacts from noise, such as startling and temporary displacement, no adverse effects to biological resources are anticipated.

Operation
Impacts to biological resources from operation of the SBX at NBVC Port Hueneme/San Nicolas would be similar to those described in section 4.6.3.2. The SBX vessel would incorporate marine pollution control devices such as keeping decks clear of debris, cleaning spills and residues, and engaging in spill and pollution prevention practices in compliance with the UNDS provisions of the Clean Water Act. No significant long-term adverse impacts are anticipated to
seabirds and shorebirds, Guadalupe fur seals, California sea lions, northern elephant and harbor seals, and sea otters or to widely distributed, open-water species such as gray and killer whales.

No adverse impacts as a result of the SBX activities are anticipated to occur within the current Channel Islands National Marine Sanctuary located off the coast south of Vandenberg AFB. Additional consultation would be performed with the National Oceanographic and Atmospheric Administration following their decision on the sanctuary boundary expansion.

4.7.3.3 Cumulative Impacts

No other projects in the ROI have been identified that would have the potential for incremental, additive cumulative impacts to biological resources in the ROI. As stated above, no effects are anticipated on whales, other marine mammals, or sea turtles that might be present in the vicinity of the homeport and transit locations.

4.7.3.4 Mitigation Measures

No biological resources mitigation measures are proposed for the GMD activities.

4.7.4 HAZARDOUS MATERIALS AND HAZARDOUS WASTE—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, NBVC PORT HUENEME

4.7.4.1 No Action Alternative

Under the No Action Alternative, the GMD ETR would not be established, and interceptor and target launch scenarios would not require the SBX for testing under operationally realistic conditions. Operations currently conducted at NBVC Port Hueneme/San Nicolas would continue.

4.7.4.2 Alternatives 1, 2, and 3

Construction

Construction of new or modification of existing facilities may result in temporary use of potentially hazardous materials and the generation of small amounts of hazardous waste. The small increases in the amount of potentially hazardous materials used during construction activities would result in an added throughput in the Supply Department. However, this increase is not expected to be significant. The Environmental Materials Management Division has a model facility which would be able to accommodate the increased hazardous materials in accordance with existing regulations.

There is an existing less-than-90-day accumulation area. If it is not adequate to handle construction requirements, other temporary areas may be designated and operated according to RCRA and state regulations. Any temporary sites would be removed at the completion of construction. There would be no significant impact on hazardous waste management from construction activities.
Operation

Shipboard Hazardous Materials and Waste Management

The U.S. Navy requires that, to the maximum extent practicable, ships shall retain hazardous waste aboard ship for shore disposal. If hazardous materials are discharged overboard, this must occur more than 370 kilometers (200 nautical miles) from land. Since all portions of the Point Mugu Sea Range are within 370 kilometers (200 nautical miles) of the California coast, shipboard discharge of hazardous materials is prohibited within range. Any hazardous waste disposal at beyond 370 kilometers (200 nautical miles) would comply with OPNAVINST 5090.1 Appendix L. Discharging hazardous materials overboard is not standard practice and would only be done as a worst-case scenario. Twenty-five liquid discharges, such as clean ballast, deck runoff and dirty ballast, from the normal operation of Armed Forces vessels are required to be controlled by installation of control technologies or use of management practices (marine pollution control devices) under the UNDS provisions of the Clean Water Act. In compliance with UNDS, the SBX vessel would incorporate marine pollution control devices, such as keeping decks clear of debris, cleaning spills and residues, and engaging in spill and pollution prevention practices, in design or routine operation.

Hazardous Materials Management

Range support operations would increase, resulting in a minor increase of hazardous materials use. The support units handling the SBX would have the capacity to do so. The small increases in the amount of hazardous materials used due to increased support operations would result in an added throughput in the Supply Department. However, this increase is not expected to be significant. The Environmental Materials Management Division has a model facility which would be able to accommodate the increased hazardous materials in accordance with existing regulations.

Fuels (jet fuel and unleaded gasoline) are stored in ASTs on San Nicolas Island. Current throughput is approximately 15,142 liters (4,000 gallons) of unleaded gasoline and 189,271 liters (50,000 gallons) of jet fuel per month. Impacts from the Proposed Action are most likely to arise from an increase in the amount of fuel required for SBX support and operation. Impacts to fuel storage and throughput from implementation of the Proposed Action would be less than significant.

Hazardous Waste Management

San Nicolas Island manages approximately 29,813 kilograms (65,689 pounds) of hazardous waste annually (Naval Air Weapons Center, Point Mugu, 1998). Hazardous waste generated by the SBX would be stored at one of the eight satellite hazardous waste accumulation areas on the island before being transported to the less-than-90-day accumulation area. It is expected that these accumulation areas would be able to accommodate the quantity of hazardous waste generated by the SBX. No significant long-term adverse impacts are anticipated to current hazardous waste management practices.

4.7.4.3 Cumulative Impacts

No other projects in the ROI have been identified that would have the potential for incremental, additive cumulative impacts to existing hazardous materials and waste management practices.
4.7.4.4 Mitigation Measures
No hazardous materials/hazardous waste management mitigation measures are proposed for the GMD ETR activities.

4.7.5 HEALTH AND SAFETY—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PORT HUENEME

4.7.5.1 No Action Alternative
Under the No Action Alternative, the GMD ETR would not be established and interceptor and target launch scenarios would not require the SBX for testing under operationally realistic conditions. Operations currently conducted at NBVC Port Hueneme/San Nicolas would continue.

4.7.5.2 Alternatives 1, 2, and 3

Construction
Any construction or facility modification required to support the SBX would occur in accordance with existing installation safety protocol/plans and applicable state and federal requirements. No adverse effects to health and safety of construction contractors or the public are anticipated.

Operation
The SBX operating area would be in the vicinity of the mooring location at San Nicolas Island, as shown in figure 2.3.1-14. Configuration and general operation of the SBX would occur as described in section 2.1.4. The transmit/receive RF emission pattern would be mostly contained within a narrow main beam. The total duration of RF radiation per week would be approximately 5 to 6 hours.

An EMR/EMI survey and analysis would be conducted by the Joint Spectrum Center that considers HERP, HERF, and HERO. The survey is used in preparing a DD Form 1494 that would be required as part of the spectrum certification and frequency allocation process. The completed DD Form 1494 that has been processed and approved by the appropriate national and international authorities would be required prior to SBX testing.

The analysis provides recommendations for sector blanking and safety systems to minimize exposures. The proposed systems would have the appropriate safety exclusion zones established before operation, and warning lights to inform personnel when the system is in operation and emitting EMR. Mechanical and software stops would be used to prevent the main beam from being directed in specified sectors where it may present a hazard.

Potential health and safety impacts related to human exposure, EEDs, fuels, communications—electronics interference, and aircraft avionics would be similar to those described in section 4.3.5.2.5. Appendix G also provides summary information regarding potential SBX EMR issues.

Implementation of SBX operational safety procedures, including establishment of controlled areas and limitations in the areas subject to illumination by the radar units, would preclude any potential safety hazard to either the public or workforce from exposure to EMR. SBX operations would be coordinated with the FAA, Coast Guard, and other groups or agencies as appropriate.
Therefore, no health and safety impacts to coastal areas, airspace/aircraft, or mariners are anticipated.

4.7.5.3 Cumulative Impacts
The concept of time averaging is important in consideration of the potential cumulative exposures that might occur near operating radars. Because tracking and search radar beams move rapidly, depending on the particular mission or exercise, it is unlikely that environmental exposures would ever consist of continuous, constant values of power density. Rather, almost universally, exposures would be intermittent and, when the radars are transmitting, the electromagnetic fields would be constantly changing in intensity. Thus, the potential for additive, incremental cumulative impacts from EMR exposure is extremely limited. No other projects in the ROI have been identified that would have the potential for incremental, additive cumulative impacts to health and safety.

4.7.5.4 Mitigations
Limitations imposed on the range of azimuth and angles of operation would preclude potential impacts related to health and safety. Mechanical and software stops would be used to control the radar’s operation.

4.7.6 UTILITIES—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PORT HUENEME
4.7.6.1 No Action Alternative
Under the No Action Alternative, the GMD ETR would not be established, and the SBX would not be developed to support interceptor and target launch scenarios, needed for operationally realistic test conditions. NBVC Port Hueneme and San Nicolas Island would continue their current operations.

Energy
Daily average demand for electricity at NBVC Port Hueneme is 8,000 kW, amounting to only 18.2 percent of total capacity. During summer peaks, the typical demand of 13,000 kW equates to approximately 30 percent of capacity.

Water
Potable water consumption at NBVC Port Hueneme is an average of 6.1 million liters (1.6 million gallons) per day, or 27.7 percent of the City of Port Hueneme’s total 22.0-million-liter (5.8-million-gallon) per day capacity; this accounts for approximately 30 percent of the total daily demand on the city system of 20.06 million liters (5.3 million gallons).

Wastewater
Wastewater generation at NBVC Port Hueneme is 1.8 million liters (480,000 gallons) per day, or 12 percent of its total capacity of 22.0 million liters (5.8 million gallons) per day.

Solid Waste
Solid waste disposal at NBVC Port Hueneme is handled by landfill and shipping offsite. It is anticipated the landfill in question would operate for another 30 years at the present rate of
waste generation, with its capacity currently at 4 million cubic meters (30 million cubic yards). NBVC Port Hueneme generation levels are at 16 metric tons (18 tons) per day.

4.7.6.2 Alternatives 1, 2, and 3

All of the alternatives would include SBX as one of the components of the Proposed Action. The operation of SBX would require BOA and a PSB.

Electrical power requirements for the SBX platform and its various payloads would be approximately 21.8-MW, supplied by six on-board 3.64-MW generators. The SBX would be self-propelled by two of four steerable 3.4-MW electric thrusters that would effectively drive and maneuver the SBX without assistance. During transportation, these retractable, Z-drive thrusters would consume approximately 7 MW, leaving 14.8 MW available for necessary shipboard operations, as well as the XBR.

The SBX has a fuel capacity of approximately 3,100,000 liters (818,000 gallons). The approximate fuel consumption for transit and radar operation is 54,800 liters (14,500 gallons) per day, which would only amount to approximately 1.8 percent of total fuel capacity daily. Fuel consumption at the mooring site would be approximately 11,350 liters (3,000 gallons) per day.

There would be a total of 50 crew members, including 20 marine crew and 30 GMD mission support personnel. Additionally, up to 50 people could be accommodated on board on a temporary daytime basis.

At the intervals between GMD test missions, the SBX would return to a PSB or adjacent mooring location for crew rotations, re-supply, and maintenance activities. While at an adjacent mooring location, three of the six generators would still be used, one operating continually while in port for daily ship functions, while the remainder would power the half- or fully populated radar 3 hours per day.

The latter scenario would apply at NBVC Port Hueneme, which is not deep enough to permit SBX entry; however, the harbor can host a resupply ship to service the SBX (delivering food, supplies, repair parts, and fuel), which would be moored just off San Nicolas Island. NBVC Port Hueneme routinely provides underway replenishment operations in support of test operations. Personnel would be ferried to the SBX each day either by watercraft or helicopter. Currently there is no fuel pier at San Nicolas Island. Fuel is delivered by pipeline from a moored location. There is a Military Construction Project for a pier due to be complete in late 2003 that would be suitable for SBX resupply vessel operations.

Existing warehouses at NBVC Port Hueneme would possibly be renovated for SBX use. Should these nearby facilities prove inadequate to accommodate a maximum of 25 personnel, construction of new storage and administration facilities would be necessary. If existing facilities are used, security upgrades, environmental controls for storage areas, fueling capability, ship gases handling facilities, computer networks, phone systems, and hazardous material storage and disposal may be added. Ongoing logistics and support operations such as re-supply, fueling and maintenance, and crew/operator training would also occur at the PSB.
Studies have shown an average 189 liters (50 gallons) per capita per day water consumption and 170 liters (45 gallons) per capita per day of wastewater production. Recent figures indicate that in the United States, the per capita generation of municipal solid waste in 1998 was 2 kilograms (4.46 pounds) per capita per day (U.S. Environmental Protection Agency, Region 9, 2002). Average daily demand for water, wastewater, and municipal solid waste for a maximum 25 personnel would be estimated as follows, based on typical usage: 4,725 liters (1,250 gallons) water; 4,258 liters (1,125 gallons) wastewater and 50 kilograms (112 pounds) of solid waste. Any new facilities being constructed would be required to facilitate this level of use, as well as to accommodate any energy demand.

4.7.6.3 Cumulative Impacts

At this time, there are no ongoing or foreseeable future programs/plans identified in the ROI that, when combined with the relatively minor SBX utility requirements, would result in cumulative impacts to utilities. Therefore, no cumulative impacts are anticipated with Alternatives 1, 2, and 3.

4.7.6.4 Mitigation Measures

No utilities mitigation measures are proposed for the GMD ETR activities.
4.8 NAVAL STATION EVERETT—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE

4.8.1 AIR QUALITY—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, NAVAL STATION EVERETT

4.8.1.1 No Action Alternative

Under the No Action Alternative, the GMD ETR would not be established, and interceptor and target launch scenarios would not require the SBX for testing under operationally realistic conditions. Operations currently conducted at Naval Station Everett would continue. Table 4.8.1-1 lists the existing emissions in the vicinity of Naval Station Everett.

Table 4.8.1-1: Maximum Measured Pollutant in Naval Station Everett Vicinity

Source: Puget Sound Clean Air Agency, 2000, 2001

4.8.1.2 Alternatives 1, 2, and 3

Construction

Construction and facility modification required to provide support to the SBX would occur in previously disturbed areas. Frequent rains common to the area would minimize dust and PM-10 formation. Dust suppression measures such as periodic watering of areas being graded, minimizing unnecessary traffic, reducing vehicle speeds near the work areas, and wet sweeping, or otherwise removing soil and mud deposits from paved roadways and parking areas, would be used as required. All construction would be conducted in accordance with the appropriate permits and regulations. No exceedences of the NAAQS or state AAQS would be anticipated.

Operation

Operational emissions aboard the SBX would be limited to the exhaust produced by generators and maintenance. Maintenance-related emissions would include minimal levels of volatile organic compound emissions that are not expected to have a significant impact on air quality.

65 Percent and Fully Populated SBX

Based on five tests per year the SBX would be at the Naval Station Everett PSB for 7 months. For conservative analysis purposes, 9 months will be used. The SBX is being analyzed as a mobile source with an expected use of 1,650 hours per year (3 hours a day for 9 months) docked at Naval Station Everett. The SBX on-board power plant planned for use would include eight 3.64-MW diesel driven generators. While at the PSB, only two of the generators would be
used. These generators would be required for powering of the 65 percent or fully populated radar for 3 hours per day. This represents 1,650 hours (825 hours each) of operation for the two generators that would be in operation while the SBX is at Naval Station Everett. Total power output for the two 3.64-MW generators would be 6,006 MW hours for the time the SBX is at the PSB. The SBX would not be considered a stationary source at Naval Station Everett; therefore, neither a Prevention of Significant Deterioration review nor a Title V permit would be required.

The remaining 3 months of the year it is expected the SBX would be in transit or at one of the SBX operating areas in the BOA.

### 4.8.1.3 Cumulative Impacts

Cumulative impacts at Naval Station Everett would include the use of generators while the SBX is docked, as well as the possible increase in vehicle trips due to the number of personnel and deliveries required for the SBX. Since Snohomish County has been identified as being in non-attainment, it must be assumed that any emissions have the potential to impact the surrounding area. The Clean Air Act, as amended in 1990, requires that, in non-attainment areas, federal actions conform to the appropriate State Implementation Plan; however the SBX is not considered a stationary source as defined in the Clean Air Act and would not require permitting.

### 4.8.1.4 Mitigation Measures

No air quality mitigation measures are proposed for GMD ETR activities.

### 4.8.2 AIRSPACE—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, NAVAL STATION EVERETT

#### 4.8.2.1 No Action Alternative

Under the No Action Alternative, the GMD ETR would not be established, and interceptor and target launch scenarios would not require the SBX for testing under operationally realistic conditions. Operations currently conducted at Naval Station Everett would continue.

#### 4.8.2.2 Alternatives 1, 2, and 3

The Proposed Action related to airspace would be full power emissions from the SBX while at the pier location at Naval Station Everett.

**Operation**

*Controlled and Uncontrolled Airspace*

Unrestricted operation of the SBX at the pier location would have the potential to adversely affect air operations. As discussed in section 4.3.2.2.1, the SBX would not exceed military aircraft interference standards or the FAA standard for peak power levels. The SBX could exceed the 300 V/m average power threshold. The average power threshold is based upon reducing the time of exposure of aircraft avionics (electronic equipment) to High Intensity Radiated Fields in order to preclude shortening the life of the aircraft avionics. Therefore, the concern is not interference but is a reduction in life of the aircraft avionics. As shown in table 2.1.4-2, the fully populated radar has a potential for interference with aircraft (exceeding the 300 V/m average power threshold) out to a distance of 19 kilometers (11.8 miles) from the SBX.
In order to avoid or minimize adverse effects from EMR/EMI, DoD has established a coordination process with responsible agencies and airspace users. A full EMR/EMI survey and analysis would be conducted by the Joint Spectrum Center, in coordination with the FAA, DOT, and other potentially affected users. The survey is used in preparing a DD Form 1494 that would be required as part of the spectrum certification and frequency allocation process. The completed DD Form 1494 that has been processed and approved by the appropriate national and international authorities would be required prior to SBX testing.

The results of the survey would also be used to define the operating area for the SBX (acceptable azimuths and operating angles). The maximum operating area would be all azimuths (360 degrees), and all angles up to 90 degrees. The maximum potential interference distances are listed in table 2.1.4-2 and are shown on figure 3.8.2-1.

The actual SBX operating area at the pier location would be restricted in order to minimize impacts to aircraft operations, EEDs, and communication equipment. A high energy radiation area notice would be published on the appropriate aeronautical charts, notifying aircraft of a RF radiation area. The boundaries of the SBX high energy radiation area would be configured to minimize impacts to aircraft operations and other potentially affected systems. The establishment of this high energy radiation area would not impose any new flight restriction requirements.

SBX operations would be coordinated with the FAA and would be scheduled to occur during hours of minimal aircraft operations if possible. In addition, the SBX would utilize a real-time link to the FAA operations radar to ensure the airspace is clear of any aircraft. Consequently, there would be no reduction in the amount of navigable airspace, and thus no impacts to the controlled and uncontrolled airspace in the ROI would result.

Special Use Airspace
There is no special use airspace within the ROI. Consequently, there would be no impacts to special use airspace.

En Route Airways and Jet Routes
Two low altitude air routes (V-23 and V-287) enter the ROI and terminate at Paine Airport.

Both air routes cross the 65 percent and fully populated radar aircraft interference areas. There may be additional approach and departure routes within the ROI that would also need to be considered when defining the SBX operating area. The SBX would be programmed to limit RF emissions in the direction of airways that pass within the potential interference distance. In addition, since the radar beam is in constant motion, should an aircraft enter the interference area, it is highly unlikely that the SBX would illuminate an aircraft long enough to affect the onboard electronics.

Airports and Airfields
Seattle-Tacoma International Airport is located approximately 60 kilometers (37 miles) south of Naval Station Everett outside the ROI. Snohomish County (Paine) Airport is about 8 kilometers (5 miles) southwest of Naval Station Everett. Class D airspace above Paine Airport extends to near Naval Station Everett, with the edge of a class E airspace extension above Naval Station...
Everett. Several other airfields are located within the ROI including Harvey, Heineck, Large, Frontier, Arlington, and Whidbey.

Airports with traffic control radars would be major factors in the EMR/EMI survey and analysis and subsequent operating permit. Operation of the SBX has the potential to interfere with both aircraft systems and air navigation systems. However, the establishment of the high-energy radiation area would not impose any flight restriction requirements and would not change any airfield/airport arrival and departure traffic flows.

Most air navigation facilities within the airspace ROI would operate at lower frequencies (in the megahertz range) than the X-band SBX, and would not normally experience any interference from the SBX. Nevertheless, there is the potential for interference from the grating (side) lobes and the main beam. Section 4.8.5 (Health and Safety) provides a detailed discussion of the potential for electronic communications (in-band and adjacent band) and harmonic band RF interference, as well as non-frequency-related interference (high power effects).

Emissions from the XBR may also potentially degrade the overall system performance of in-band airborne systems such as fire control, bomb/navigation in military aircraft, and weather radars in both civilian and military aircraft, which all operate in the X-band (8 to 12 GHz). However, the SBX high-energy radiation area would be configured to minimize impacts to these airborne and ship-based systems.

4.8.2.3 Cumulative Impacts
Because the SBX operates in different frequency ranges than most aircraft radars, there would be limited potential for an incremental, additive cumulative electromagnetic effect upon the operation of an air navigation facility or the signal used by aircraft. Moreover, the frequency allocation operating permit process would take into consideration potential impacts on other resources in the region and would preclude the potential for cumulative impacts.

No other projects in the airspace ROI have been identified that would have the potential for other incremental, additive cumulative impacts to controlled or uncontrolled airspace, special use airspace, en route airways and jet routes, or airfields and airports in the ROI.

4.8.2.4 Mitigation Measures
The actual SBX operating area at the pier location would be restricted in order to minimize impacts to aircraft operations, EEDs, and communication equipment. In addition to charting the SBX high-energy radiation area notice, information would be published in the Airport Facility section of the FAA Airport Guide, and local NOTAMs would be issued to notify pilots of the high-energy radiation area. The boundaries of the SBX high-energy radiation area would be configured to minimize impacts to aircraft operations and other potentially affected systems. Additionally, flight service personnel would brief pilots flying in the vicinity about the SBX high-energy radiation area.
4.8.3 BIOLOGICAL RESOURCES—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, NAVAL STATION EVERETT

4.8.3.1 No Action Alternative
Under the No Action Alternative, the GMD ETR would not be established, and interceptor and target launch scenarios would not require the SBX for testing under operationally realistic conditions. Operations currently conducted at Naval Station Everett would continue.

4.8.3.2 Alternatives 1, 2, and 3

Construction
Any construction or facility modification required to provide support to the SBX would occur in previously disturbed areas in accordance with host installation guidelines and regulations. Although eel grass areas could be impacted by the shadow of the SBX, this would not be an issue at the depths to which the SBX is limited. Other than minor, short-term impacts from noise, such as startling and temporary displacement, no adverse effects to biological resources are anticipated.

Operation
Impacts to biological resources from operation of the SBX at Naval Station Everett would be similar to those described above in sections 4.3.3.3 and 4.6.3.2. The SBX vessel would incorporate marine pollution control devices such as keeping decks clear of debris, cleaning spills and residues, and engaging in spill and pollution prevention practices in compliance with the UNDS provisions of the Clean Water Act. No significant long-term adverse impacts are anticipated to seabirds, shorebirds (bald eagle), Chinook salmon, bull trout, or widely distributed, open-water species such as humpback, blue, fin, sei, and sperm whales; green, leatherback, and loggerhead sea turtles; and steller sea lions.

4.8.3.3 Cumulative Impacts
No other projects in the ROI have been identified that would have the potential for incremental, additive cumulative impacts to biological resources in the ROI. As stated above, no effects are anticipated on whales, other marine mammals, or sea turtles that might be present in the vicinity of the homeport and transit locations.

4.8.3.4 Mitigation Measures
No biological resources mitigation measures are proposed for GMD ETR activities.

4.8.4 HAZARDOUS MATERIALS AND HAZARDOUS WASTE—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, NAVAL STATION EVERETT

4.8.4.1 No Action Alternative
Under the No Action Alternative, the GMD ETR would not be established and interceptor and target launch scenarios would not require the SBX for testing under operationally realistic conditions. Operations currently conducted at Naval Station Everett would continue.
4.8.4.2 Alternatives 1, 2, and 3

Construction

Any construction or facility modification required to provide support to the SBX would occur in previously disturbed areas in accordance with host installation guidelines and regulations. Other than minor, short-term increase from the use of potentially hazardous materials such as paints, solvents, and fuels, no adverse effects to ongoing hazardous materials storage and handling are anticipated. The small increases in the amount of potentially hazardous materials used during construction activities would result in generation of added wastes. However, this increase is not expected to be significant and would be accommodated in accordance with existing protocol and regulations.

Operation

Shipboard Hazardous Materials and Waste Management

The Navy requires that, to the maximum extent practicable, ships shall retain hazardous waste aboard ship for shore disposal. If hazardous materials are discharged overboard, this must occur more than 370 kilometers (200 nautical miles) from land. Any hazardous waste disposal beyond 370 kilometers (200 nautical miles) would comply with OPNAVINST 5090.1 Appendix L. Discharging hazardous materials overboard is not standard practice and would only be done as a worst-case scenario.

Twenty-five liquid discharges, such as clean ballast, deck runoff, and dirty ballast, from the normal operation of Armed Forces vessels are required to be controlled by installation of control technologies or use of management practices (marine pollution control devices) under the UNDS provisions of the Clean Water Act. In compliance with UNDS, the SBX vessel would incorporate marine pollution control devices, such as keeping decks clear of debris, cleaning spills and residues and engaging in spill and pollution prevention practices, in design or routine operation.

Range

Increased operations that could take place at Naval Station Everett would be servicing and maintenance of the SBX. This small increase in servicing operations would not significantly affect hazardous materials management or waste disposal. There would be no significant operational impacts.

4.8.4.3 Cumulative Impacts

No other projects in the ROI have been identified that would have the potential for incremental, additive cumulative impacts to existing hazardous materials and waste management practices.

4.8.4.4 Mitigation Measures

No hazardous materials/hazardous waste management mitigation measures are proposed for GMD ETR activities.
4.8.5 HEALTH AND SAFETY—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, NAVAL STATION EVERETT

4.8.5.1 No Action Alternative

Under the No Action Alternative, the primary support base for the SBX would not be located at Naval Station Everett. Operations currently conducted at Naval Station Everett Harbor would continue.

4.8.5.2 Alternatives 1, 2, and 3

Construction

Any construction or facility modification required to support the SBX would occur in accordance with existing installation safety protocol/plans and applicable state and federal requirements. No adverse effects to health and safety of construction contractors or the public are anticipated.

Operation

The SBX operating area would be in the vicinity of Pier Alpha or Pier Bravo at Naval Station Everett, as shown in figure 2.3.1-15. Configuration and general operation of the SBX would occur as described in section 2.1.4. The transmit/receive RF emission pattern would be mostly contained within a narrow main beam. The total duration of RF radiation per week would be approximately 5 to 6 hours.

An EMR/EMI survey and analysis would be conducted by the Joint Spectrum Center that considers HERP, HERF, and HERO. The survey is used in preparing a DD Form 1494 that would be required as part of the spectrum certification and frequency allocation process. The completed DD Form 1494 that has been processed and approved by the appropriate national and international authorities would be required prior to SBX testing.

The analysis provides recommendations for sector blanking and safety systems to minimize exposures. The proposed systems would have the appropriate safety exclusion zones established before operation, and warning lights to inform personnel when the system is in operation and emitting EMR. Mechanical and software stops would be used to prevent the main beam from being directed in specified sectors where it may present a hazard.

Potential health and safety impacts related to human exposure, EEDs, fuels, communications—electronics interference, and aircraft avionics would be similar to those described in section 4.3.5.2.5. Appendix G also provides summary information regarding potential SBX EMR issues.

The actual operating area of SBX at the pier location would be restricted to minimize impacts. SBX operations would be coordinated with the FAA, Coast Guard and other groups or agencies as appropriate. Therefore, no health and safety impacts to coastal areas, airspace/aircraft or mariners are anticipated.

4.8.5.3 Cumulative Impacts

The concept of time averaging is important in consideration of the potential cumulative exposures that might occur near operating radars. Because tracking and search radar beams move rapidly, depending on the particular mission or exercise, it is unlikely that environmental
exposures would ever consist of continuous, constant values of power density. Rather, almost universally, exposures would be intermittent and, when the radars are transmitting, the electromagnetic fields would be constantly changing in intensity. Thus, the potential for additive, incremental cumulative impacts from EMR exposure is extremely limited.

4.8.5.4 Mitigations
Limitations imposed on the range of azimuth and angles of operation would preclude potential impacts related to health and safety. Mechanical and software stops would be used to control the radar’s operation.

4.8.6 SOCIOECONOMICS—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, NAVAL STATION EVERETT

4.8.6.1 No Action Alternative
Under the No Action Alternative, the primary support base for the SBX would not be located at Naval Station Everett. Operations currently conducted at Naval Station Everett would continue. No displacement of populations, residences, or businesses would occur within the City of Everett or adjacent areas as a result of the No Action Alternative. The facilities would continue to be utilized as currently designated.

This alternative would not provide a positive impact upon the local economy through additional ongoing test based employment opportunities and related resultant infusion of monies through a variety of channels into the local economy. No significant impacts to locally significant businesses or industries such as aerospace, technology, or shipping are anticipated with the No Action Alternative. No significant socioeconomic impacts would occur, and no mitigation measures are proposed.

4.8.6.2 Alternatives 1, 2, 3

Construction
Implementation of Alternative 1 would result in limited construction and facility modification to provide support to the SBX, to occur at existing pier and warehouse facilities within Naval Station Everett. Since the extent of construction required at Naval Station Everett would be limited, and the SBX platform would be constructed entirely in Europe and then towed to the operational base, the economic impact of construction to the surrounding community in the form of local expenditure on basic building materials, limited use of local contractors, and also related spending through wages by specialist contractors would be positive but relatively limited.

Construction activities related to the related to the implementation of Alternative 1 would not cause any displacement of populations, residences, or businesses within the city of Everett and surrounding areas. The duration of construction activities would be temporary and would be expected to last several months. The accommodation needs of the non-local construction personnel during this period would be adequately met via local hotels and guesthouses. Given the extent of available lodging facilities within the City of Everett, the presence of additional construction personnel would not be considered a potentially significant impact.

By spending money in the local economy, mainly via accommodation and procurement of goods and services, the additional construction personnel associated with the Proposed Action would
represent both a potential increase in local service-based employment opportunities and a small but positive temporary economic impact to the local economy. The overall impact would however, be slight and would not cause any population growth. No significant impacts to locally significant businesses or industries such as aerospace, technology, or shipping are anticipated. No significant socioeconomic impacts would occur through the construction activities associated with Alternatives 1, 2, or 3.

**Operation**

Implementation of Alternative 1, 2, or 3 would result in a large sea-based platform located at Pier Alpha or Bravo at Naval Station Everett. Based on an assumption of a total of five tests per year, the SBX would be at the Naval Station Everett for a total of approximately 7 months annually. For a given test, the SBX would have a basic crew of 50 people, which currently includes approximately 20 marine crewmembers and 30 GMD mission support personnel. In addition, the SBX could accommodate an additional 50 people associated with the SBX on a temporary basis to support testing. Approximately 10 to 12 days before a GMD test mission, the SBX would leave the PSB to travel to the designated performance region.

While in port prior to a test operation, personnel would reside offsite at local hotels and guesthouses. The accommodation needs of approximately 50 additional personnel would be adequately met through the numerous lodging facilities within the city of Everett. Generally, by spending money in the local economy mainly via accommodations and the normal procurement of goods and services, the additional test related personnel would represent both a potential increase in local service based employment opportunities and a positive economic impact to the local community for the duration of time spent at the facility. The overall economic impact through this, while moderate regionally, would still represent a positive cumulative economic impact of several million dollars to the Everett economy. The proposed project would not cause any population growth. No population, housing, or businesses would be displaced during operational activities.

The SBX would be approximately 76 meters (250 feet) tall with the platform 119 meters long (390 feet) and 73 meters (238 feet) wide and moored at Naval Station Everett for about 6 weeks at a time for a total of 7 months of the year. Given the physical proportions, proposed location, and duration of time in port of the SBX, the proposed project could represent potentially adverse visual impacts to the waterfront view of a number of residential areas and businesses surrounding the base, potentially leading to commercial and residential property value impacts, as well as an influence on tourism.

As outlined in section 4.8.8.2 (Visual and Aesthetic Resources), Naval Station Everett is also home to the naval aircraft carrier *USS Abraham Lincoln*. *USS Abraham Lincoln* has a much greater length than the SBX; however, the SBX is taller and not as sleek as the aircraft carrier. The SBX would be moored at Pier Alpha or Pier Bravo, either in the location currently occupied by *USS Abraham Lincoln* when it is at sea or on the other side of Pier Alpha when *USS Abraham Lincoln* is in port. Also, Naval Station Everett is adjacent to several industrial land uses, such as a large paper mill and manufacturing areas. Visual impacts to the surrounding area would be partially mitigated by the fact that the SBX would be an additional structure on an existing military base immediately surrounded by industrial land uses, thereby reducing the potential impacts to commercial and residential property values.
Other potential project-related economic impacts concern impacts to property values of residences and businesses within the areas surrounding the base, pertaining to the in port use, and perceived threats to human health by EMR associated with the proposed project.

The proposed SBX operating conditions would include full power operation to track objects in space. The beam would be pointed up and constantly moving along with the object. Software controls would not allow a full power beam to come in contact with any personnel on the platform or on land. Similar software controls have been proven and effectively used on the large X-band radar operating at Kwajalein Island in the RMI. The disruption of pacemakers via RF radiation has been studied extensively by the U.S. Air Force and Georgia Technical Research Institute, and the SBX would not exceed the 10 mW/cm² those agencies determined would be required to affect pacemakers.

The SBX would not exceed the 3,000 volts per meter peak power threshold for commercial aircraft as established by the Federal Aviation Administration. The SBX can exceed the 300 volts per meter average power threshold; however, the concern here would not be interference but rather a reduction in life of the aircraft avionics.

As outlined in section 4.8.5, Health and Safety, based on the current standards and documented analysis referenced above, the proposed operation of the SBX in port, with appropriate controls and coordination, would not pose a hazard to personnel or equipment.

Everett is also in the process of redeveloping an area on the northern side of the marina. The Port of Everett North Marina Redevelopment Master Plan (Maritime Trust Company, 2002) would include the addition of residential, commercial, and recreational areas within the northern part of the marina near the existing North Marina. Figure 4.8.6-1 shows where the Redevelopment Plan project study area is in relation to the potential SBX locations. While it is possible that those that visit and reside in this area may be affected by the SBX, the effects would be minimal. The potential SBX site is over 1 mile (1.6 kilometers) from the North Marina and the view of the SBX would be obstructed by existing and proposed buildings, vegetation, and docked ships. It is possible, however, that those within the southwest corner of this area would have an unobstructed view of the SBX along the channel. Due to the distance from the SBX to the redevelopment location, and the partially obstructed views, it is anticipated that the SBX would have a minimal economic impact on the redevelopment plan.

It is, however, worth noting that the perception held by many persons that project-related use of EMR does indeed pose a health risk could potentially lead to a diminished level of desirability, and therefore demand for certain properties within the areas perceived to be affected, thereby having the potential to adversely affect property values within those areas. Given that this impact would be solely attributable to individual interpretation of a perceived risk, the extent and nature of the potential fall in property values, if any, and the areas affected are unable to be determined. The assumption that the SBX would result in a reduction in property values is conjecture and does not present any quantifiable statistics or other information that can be readily or credibly analyzed. In addition, real estate values in an area are more directly related to the levels of income and employment that occur in the area. Socioeconomic studies prepared by the U.S. Air Force and the military's experience during several rounds of base closures have shown that housing values and military programs are generally positively related.

North Marina Redevelopment Plan Project Study Area and Potential SBX Locations

Everett, Washington

Figure 4.8.6-1
Particularly in a port area where the mooring of ships and other Navy activities are a normal incidence of the military presence, a reduction of property values from the visual effect of large vessels in the harbor, or a perceived risk, does not seem likely.

In transit to and from the test site, coordination with marine traffic would be adequately advertised through a NOTMAR in order to prevent any conflicts with tribal fishing areas, and to prevent any impacts on current shipping schedules, ship-borne commerce, recreational boating, or general transit. As outlined in section 4.8.6.1 Naval Station Everett is located close to the port and provides easy access to the main channel of Puget Sound. Commercial tugboats would be utilized for this purpose.

At the test site, and while in port, SBX operations would be coordinated with the FAA and would be scheduled, if possible, to occur during hours of minimal aircraft operations. There would no reduction in the amount of the navigable airspace, no disruption of existing aircraft operation would be foreseen, and no resultant economic impacts are expected.

4.8.7 TRANSPORTATION—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, NAVAL STATION EVERETT

4.8.7.1 No Action Alternative

Under the No Action Alternative, the GMD ETR would not be established, and interceptor and target launch scenarios would not require the SBX for testing under operationally realistic conditions. Operations at Port Everett would continue as currently conducted.

4.8.7.2 Alternatives 1, 2, and 3

All of the alternatives would include SBX as one of the components of the Proposed Action.

Construction

Any construction or facility modification required to provide support to the SBX would occur in previously disturbed areas, and in accordance with host installation guidelines and regulations. As excess warehouse and administrative space is available, there is the possibility that no new construction would be necessary. No adverse effects to transportation resources are anticipated.

Operation

The SBX would be required to meet environmental requirements for commercial vessels.

At Naval Station Everett, both Pier Alpha (the primary ship berthing facility) and Pier Bravo could be used for the SBX and would be coordinated with the naval station. *USS Abraham Lincoln*, a Nimitz-class aircraft carrier that utilizes the naval station as a homeport, is out of port approximately 6 months out of each year.

Naval Station Everett provides easy access to the main channel of Puget Sound. At least two tugboats would be required to assist the SBX when in port. However, Naval Station Everett has no tugboat complement of its own, and thus tugs used at the port are primarily commercial (GlobalSecurity.org, 2002b).
Such activities are typical for Port Everett and, as with all such shipping issues, would require coordination with the U.S. Coast Guard. Requests for tugs must be made 72 hours in advance of anticipated time of movement, and are handled by the Senior Officer Present Afloat Puget Sound (GlobalSecurity.org, 2002b). Adequate coordination with the Tulalip Tribes would prevent any conflicts with tribal fishing areas (Naval Station Everett, 2003). Coordination with the Coast Guard and the Port of Everett would prevent any impacts on current shipping schedules, ship-borne commerce, or general transit (Miller, 2002).

No additional security standoff would be required while the SBX is at Naval Station Everett. The SBX would be within the existing exclusion zone that varies from no standoff along the western side of Pier Bravo to a 91 meter (300 foot) standoff along the southern end of Pier Alpha and Pier Bravo, to a 182 meter (600 foot) standoff along the eastern side of Pier Alpha. Once underway, the SBX security zone would be similar to the Navy vessel protection zone that applies to Navy vessels that are underway. This moving zone includes a 91.4-meter (100-yard) security exclusion zone around the vessel and a slow speed zone between 91.4 and 457 meters (100 and 500 yards) from the vessel.

Some 20 people would be instated at the PSB. As many as 50 personnel could leave the SBX for onshore activities. Even given a maximum, and extreme case, of 50 automobile trips per day, this level would be less than a 0.59 percent over the current level of 8,520 vehicle trips generated by Naval Station Everett per day. No impacts to area roadways are expected.

Cumulative Impacts
No other projects in the ROI have been identified that would have the potential for incremental, additive cumulative impacts to transportation in the ROI.

Mitigation Measures
No transportation mitigation measures are proposed for GMD ETR activities.

4.8.8 UTILITIES—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, NAVAL STATION EVERETT

4.8.8.1 No Action Alternative
Under the No Action Alternative, the GMD ETR would not be established and the SBX would not be developed to support interceptor and target launch scenarios, needed for operationally realistic test conditions. Naval Station Everett would continue their current operations.

Energy
Daily average demand for electricity at the Naval Station Everett waterfront site is 36,000 kVA, some 45 percent of the available 80,000 kVA.

Water
Potable water consumption at the Naval Station Everett waterfront site is typically 3.4 million liters (900,000 gallons) per day, or 33.3 percent of the total available capacity of 10.2 million liters (2.7 million gallons) per day.
Wastewater
Wastewater generation at Naval Station Everett’s sanitary sewer system is typically 3.8 million liters (990,000 gallons) per day, or 33.3 percent of the available capacity of 11.4 million liters (3 million gallons) per day.

Solid Waste
Solid waste disposal at Naval Station Everett is handled by landfill and shipping offsite. The average level generated at the waterfront site and by transient Navy ships is 4.6 metric tons (4.5 tons) per day.

4.8.8.2 Alternatives 1, 2, and 3
All of the alternatives would include SBX as one of the components of the Proposed Action. The operation of SBX would require BOA and a PSB.

Electrical power requirements for the SBX platform and its various payloads would be approximately 21.8-MW, supplied by six on-board 3.64-MW generators. The SBX would be self-propelled by two of four steerable 3.4-MW electric thrusters that would effectively propel and maneuver the SBX without assistance. During transportation, these retractable, Z-drive thrusters would consume 7 MW, leaving 14.8 MW available for necessary ship-board operations, as well as the XBR.

The SBX has a fuel capacity of approximately 3.1 million liters (818,000 gallons). The approximate fuel consumption for transit and radar operation is 54,800 liters (14,500 gallons) per day, which would only amount to approximately 1.8 percent of total fuel capacity daily. Fuel consumption at the Naval Station Everett pier would be approximately 2,270 liters (600 gallons) per day.

There would be a total of 50 crew members, including 20 marine crew and 30 GMD mission support personnel. Additionally, up to 50 people could be accommodated on board on a temporary daytime basis.

At the intervals between GMD test missions, the SBX would return to a PSB for crew rotations, re-supply, and maintenance activities.

The current plan would be to moor the SBX at Pier Alpha or Bravo to allow the SBX to conduct pier-side operations. A utility hookup would be required for the SBX to run onboard lighting and other basic needs and would be utilized in lieu of a continually operating generator. Utility levels would be typical of that for other ships supplied by the Naval Station Everett piers and would be considered routine.

Currently, there is no excess warehouse or administrative space available for the PSB; however, there is adequate space for the construction of new storage and administration facilities for a maximum of 25 personnel. Due to this limited space, a new 900- to 1,500-square-meter (3,000- to 5,000-square-foot) environmentally controlled warehouse would potentially be required for SBX operations.
Studies have shown an average 189 liters (50 gallons) per capita per day water consumption and 170 liters (45 gallons) per capita per day of wastewater production. Recent figures indicate that in the United States, the per capita generation of municipal solid waste in 1998 was 2 kilograms (4.46 pounds) per capita per day (U.S. Environmental Protection Agency, Region 9, 2002). Average daily demand for water, wastewater, and municipal solid waste for a maximum 25 personnel would be estimated as follows, based on typical usage: 4,725 liters (1,250 gallons) water; 4,258 liters (1,125 gallons) wastewater and 50 kilograms (112 pounds) of solid waste. Any new facilities being constructed would be required to facilitate this level of use, as well as to accommodate any energy demand.

4.8.8.3 Cumulative Impacts

At this time, there are no ongoing or foreseeable future programs/plans identified in the ROI that, when combined with the relatively minor SBX utility requirements, would result in cumulative impacts to utilities. Therefore, no cumulative impacts are anticipated with Alternatives 1, 2, and 3.

4.8.8.4 Mitigation Measures

No utilities mitigation measures are proposed for GMD ETR activities.

4.8.9 VISUAL AND AESTHETIC RESOURCES—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, NAVAL STATION EVERETT

4.8.9.1 No Action Alternative

Under the No Action Alternative, the SBX would not be located at Naval Station Everett. There would be no alteration of the existing visual setting and the adjacent area. No significant impacts to visual and aesthetic resources would occur.

4.8.9.2 Alternatives 1, 2, and 3

Visual resources could be affected by the proposed SBX at Naval Station Everett. The SBX would be approximately 76 meters (250 feet) tall, and the SBX platform would be 119 meters (390 feet) long and 73 meters (238 feet) wide. The SBX would be located at Naval Station Everett for about 6 weeks at a time, a total of 7 months per year.

In an effort to determine the existing visual quality of each of the SBX locations, the following method was modified from “Landscape Aesthetics: A Handbook for Scenery Management” (U.S. Department of Agriculture, U.S. Forest Service, 1995). The handbook outlines ways to measure individual aspects of visual resources and then rate the scenic value class of each of the locations. The following criteria were used to determine the scenic value class for the potential SBX locations: scenic attractiveness, viewer concern, and distance zones. Scenic attractiveness is the measure of scenic quality based on human perceptions of inherent beauty of the forms, colors, textures, and visual composition of an individual landscape. Viewer concern can be defined as the level of scenic importance based on expressed human concern for the scenic quality of land areas viewed. The distance zone is a principal indicator of scenic importance based on the distance an area can be seen by observers, and the degree of visible detail within that zone. In addition, scenic integrity is included to determine the current level of modification to an area. A description of the scenic value rating criteria and scenic attractiveness can be found in appendix B.
The potential location for the SBX at Naval Station Everett would be pier-side at Pier Alpha or Pier Bravo. Primarily, the areas from which the SBX can be seen include residential areas, recreational areas, industrial areas, and also the Naval Base itself.

**Scenic Attractiveness**

Due to the development of the area and the lack of visual attributes the area is considered to be indistinctive (C).

**Concern Level**

The concern level of the viewers at Naval Station Everett would be considered to be “high” (Level 1) due to the recreational and residential use of the adjacent and surrounding areas.

**Distance Zone**

The potential SBX location would be within the foreground (FG) of the shoreline, the mid-ground (MG) for the residential areas, and the background (BG) for the residents of Whidbey Island. However, it is very unlikely that residents of Whidbey Island would be able to distinguish between the SBX and Everett itself.

**Scenic Value Class**

The scenic value class for Naval Station Everett, as determined from the scenic value class table, table 4.8.9-1, would be high (1) within the foreground, moderate (2) within the mid-ground, and low (3) within the background, depending on the distance between the viewer and the SBX.

Source: (U.S. Department of Agriculture, U.S. Forest Service, 1995)

**Scenic Attractiveness**  
A – Distinctive, B – Typical, C – Indistinctive

**Distance zone and Concern Level**  
FG1 – Foreground with a high level of concern  
MG1 – Mid-ground with a high level of concern  
BG1 – Background with a high level of sensitivity  
FG2 – Foreground with a moderate level of concern  
MG2 – Mid-ground with a moderate level of concern  
BG2 – Background with a moderate level of sensitivity  
FG3 – Foreground with a low level of concern  
MG3 – Mid-ground with a low level of sensitivity  
BG3 – Background with a low level of sensitivity

**Scenic Value Class**  
1-2: High public value.  
3-5: Moderate public value.  
6-7: Low public value.
Scenic Integrity

It should also be noted that the area appears heavily altered resulting in a “very low” ranking for the level of scenic integrity.

The potential impacts to visual and aesthetics related to the SBX would be the view across the waterfront from nearby residential, recreational, and commercial areas. Aside from an area immediately adjacent to the SBX, the SBX would occupy only a small part of the horizon and panoramic views would not be inhibited. Naval Station Everett is home to *USS Abraham Lincoln*, a naval aircraft carrier, and is a port area where the mooring of ships and other Navy activities are a normal incidence of the military presence. In addition, Naval Station Everett is adjacent to industrial areas which inhibit the view of the waterfront. While there is a high amount of viewer concern, the SBX would be considered visually synonymous with the port and present military uses; therefore, only moderate impacts are expected to visual resources.

4.8.9.3 Cumulative Impacts

The SBX would be at the pier-side location intermittently throughout the year. No other activities have been identified that would contribute to cumulative impacts.

4.8.9.4 Mitigation Measures

No visual resources mitigation measures are proposed for GMD ETR activities.
4.9 PORT ADAK—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE

4.9.1 AIR QUALITY—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PORT ADAK

4.9.1.1 No Action Alternative

Under the No Action Alternative, the home port for the SBX would not be located at Port Adak. Current air emission levels would remain the same, stemming primarily from regional volcanic activity.

4.9.1.2 Alternatives 1, 2, and 3

Construction

Construction and facility modification required to provide support to the SBX would occur in previously disturbed areas. Construction activities would be conducted in accordance with all appropriate regulations and permits. Other than minor, short-term impacts from construction, no exceedances of the NAAQS or state AAQS would be anticipated.

Operation

Operational emissions aboard the SBX would be limited to the exhaust produced by generators and maintenance. Maintenance-related emissions would include minimal levels of volatile organic compound emissions that are not expected to have a significant impact on air quality.

65 Percent and Fully Populated SBX

Based on five tests per year the SBX would be at the Port Adak PSB for 7 months. For conservative analysis purposes, 9 months will be used. The SBX is being analyzed as a mobile source with an expected use of 6,600 hours per year (24 hours a day for 9 months) at a single location, approximately 3.5 kilometers (2.2 miles) from Port Adak in Finger Bay. The SBX on-board power plant planned for use would include eight 3.64-MW diesel driven generators. While at the PSB mooring location, only three of the generators would be used. One would operate continually while in port for daily ship functions. The other two generators would be required for powering the 65 percent or fully populated radar for 3 hours per day. This represents 6,600 hours of operation of one 3.64-MW generator and 1,650 (825 hours each) hours of operation for the other two generators that would be in operation at the PSB. Total power output for the three 3.64-MW generators would be 30,030 MW hours for the time the SBX is at the PSB. The SBX would not be considered a stationary source at Port Adak; therefore, neither a Prevention of Significant Deterioration review nor a Title V permit would be required.

The remaining 3 months of the year it is expected the SBX would be in transit or at one of the SBX operating areas.

It is also anticipated that the emissions would not impact the Maritime National Wildlife Refuge located on the southern portion of Adak. Due to the speed and frequency of wind on and around the island, it is expected that the emissions would disperse quickly before reaching this area.
4.9.1.3 Cumulative Impacts

Due to the limited industrialization of Adak and the surrounding environment, the potential cumulative impacts to air quality due to the proposed mooring of the SBX would not be substantial. No other projects in the ROI have been identified that would have the potential for incremental, additive cumulative impacts to the air quality in the ROI.

4.9.1.4 Mitigation Measures

No air quality mitigation measures are proposed for GMD ETR activities.

4.9.2 AIRSPACE—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PORT ADAK

4.9.2.1 No Action Alternative

Under the No Action Alternative, the GMD ETR would not be established, and interceptor and target launch scenarios would not require the SBX for testing under operationally realistic conditions.

4.9.2.2 Alternatives 1, 2, and 3

The Proposed Action related to airspace would be full power emissions from the SBX while at the mooring location at Finger Bay, south of Port Adak.

Operation

Controlled and Uncontrolled Airspace

Unrestricted operation of the SBX at the mooring location would have the potential to adversely affect air operations. As discussed in section 4.3.2.2.1, the SBX would not exceed military aircraft interference standards or the FAA standard for peak power levels. The SBX could exceed the 300 V/m average power threshold. The average power threshold is based upon reducing the time of exposure of aircraft avionics (electronic equipment) to High Intensity Radiated Fields in order to preclude shortening the life of the aircraft avionics. Therefore, the concern is not interference but is a reduction in life of the aircraft avionics. As shown in table 2.1.4-2, the fully populated radar has a potential for interference with aircraft (exceeding the 300 V/m average power threshold) out to a distance of 19 kilometers (11.8 miles) from the SBX.

In order to avoid or minimize adverse effects from EMR/EMI, DoD has established a coordination process with responsible agencies and airspace users. A full EMR/EMI survey and analysis would be conducted by the Joint Spectrum Center, in coordination with the FAA, and other potentially affected users. The survey is used in preparing a DD Form 1494 that would be required as part of the spectrum certification and frequency allocation process. The completed DD Form 1494 that has been processed and approved by the appropriate national and international authorities would be required prior to SBX testing.

The results of the survey would also be used to define the operating area for the SBX (acceptable azimuths and operating angles). The maximum operating area would be all azimuths (360 degrees), and all angles up to 90 degrees. The maximum potential interference distances are listed in table 2.1.4-2 and on figure 3.9.2-1.
The actual SBX operating area at the mooring location would be restricted in order to minimize impacts to aircraft operations, EEDs, and communication equipment. A high energy radiation area notice would be published on the appropriate aeronautical charts, notifying aircraft of a RF radiation area. The boundaries of the SBX high energy radiation area would be configured to minimize impacts to aircraft operations and other potentially affected systems. The establishment of this SBX high energy radiation area would not impose any new flight restriction requirements.

SBX operations would be coordinated with the FAA and would be scheduled to occur during hours of minimal aircraft operations. Coordination with the Anchorage ARTCC would occur prior to and during each test. Consequently, there would be no reduction in the amount of navigable airspace, and thus no impacts to the controlled and uncontrolled airspace in the ROI would result.

Special Use Airspace

There is no special use airspace within the ROI. Consequently, there would be no impacts to special use airspace.

En Route Airways and Jet Routes

The two en route low altitude airways (G8 and G1), three high altitude jet routes (J 115, J600, and J120), two great circle routes from North America to the Far East (R 336 and R451), and one military route (V 480) would be considered in defining the SBX operating area. There are additional approach and departure routes within the ROI that would also need to be considered when defining the SBX operating area. The SBX would be programmed to limit RF emissions in the airways that pass through the ROI. In addition, since the radar beam is in constant motion, should an aircraft enter the interference area, it is highly unlikely that the SBX would illuminate an aircraft long enough to affect the on-board electronics.

Airports and Airfields

Adak Airfield is located approximately 5.5 kilometers (3.4 miles) north of the proposed mooring location. With the restrictions placed on the SBX in a manner similar to the GBR-P radar at RTS, standard instrument approach and departure procedures at the airfield would continue unhindered. Existing airfield or airport arrival and departure traffic flows would also not be affected and access to the airfield would not be curtailed. All arriving and departing aircraft are under the control of the Adak Airfield Control Tower; thus, there would be no airfield conflicts in the ROI under the Proposed Action, and no impact.

There are a number of air navigation facilities within the airspace ROI. However, they operate at lower frequencies (in the megahertz range) than the X-band SBX, and would not normally experience any interference from the SBX. Nevertheless, there is the potential for interference from the grating (side) lobes and the main beam. Section 4.9.5 (Health and Safety) provides a detailed discussion of the potential for electronic communications (in-band and adjacent band) and harmonic band RF interference, as well as non-frequency-related interference (high-power effects).

Emissions from the SBX may also potentially degrade the overall system performance of in-band airborne and ship-based systems such as fire control, bomb/navigation in military aircraft, and weather radars in both civilian and military aircraft, which all operate in the X-band (8 to 12
GHz). However, the SBX high energy radiation area would be configured to minimize impacts to these airborne and ship based systems.

### 4.9.2.3 Cumulative Impacts

Because the SBX operates in different frequency ranges than most aircraft radars, there would be limited potential for an incremental, additive cumulative electromagnetic effect upon the operation of an air navigation facility or the signal used by aircraft. The use of the required scheduling and coordination process, and adherence to applicable DoD directives and U.S. Army regulations concerning radar operations would preclude the potential for significant incremental, additive, cumulative impacts.

No other projects in the airspace ROI have been identified that would have the potential for other incremental, additive cumulative impacts to controlled or uncontrolled airspace, special use airspace, en route airways and jet routes, or airfields and airports in the ROI.

### 4.9.2.4 Mitigation Measures

The actual SBX operating area at the mooring location would be restricted in order to minimize impacts to aircraft operations, EEDs, and communication equipment. In addition to charting the SBX high-energy radiation area notice, information would be published in the Airport Facility section of the *FAA Airport Guide*, and local NOTAMs would be issued to notify pilots of the high-energy radiation area. The boundaries of the SBX high-energy radiation area would be configured to minimize impacts to aircraft operations and other potentially affected systems. Additionally, flight service personnel would brief pilots flying in the vicinity about the SBX high-energy radiation area.

### 4.9.3 BIOLOGICAL RESOURCES—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PORT ADAK

#### 4.9.3.1 No Action Alternative

Under the No Action Alternative, the GMD ETR would not be established and interceptor and target launch scenarios would not require the SBX for testing under operationally realistic conditions. Operations currently conducted at Port Adak would continue.

#### 4.9.3.2 Alternatives 1, 2, and 3

**Construction**

Any construction or facility modification required to provide support to the SBX would occur in previously disturbed areas in accordance with host installation guidelines and regulations. Other than minor, short-term impacts from noise, such as startling and temporary displacement, no adverse effects to biological resources are anticipated.

**Operation**

Impacts to biological resources from operation of the SBX at Port Adak would be similar to those described above in sections 4.3.3.3 and 4.6.3.2. The SBX vessel would incorporate marine pollution control devices such as keeping decks clear of debris, cleaning spills and residues, and engaging in spill and pollution prevention practices in compliance with the UNDS provisions of the Clean Water Act. No significant long-term adverse impacts are anticipated to
area seabirds and water fowl or widely distributed, open-water species such as Steller sea lions, sea otters, harbor seals, and whales that occur around Adak Island.

4.9.3.3 Cumulative Impacts
No other projects in the ROI have been identified that would have the potential for incremental, additive cumulative impacts to biological resources in the ROI. As stated above, no effects are anticipated on whales, other marine mammals, or birds that might be present in the vicinity of the homeport and transit locations.

4.9.3.4 Mitigation Measures
No biological resources mitigation measures are proposed for GMD ETR activities at Adak.

4.9.4 HAZARDOUS MATERIALS AND HAZARDOUS WASTE—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PORT ADAK

4.9.4.1 No Action Alternative
Under the No Action Alternative, the GMD ETR would not be established, and interceptor and target launch scenarios would not require the SBX for testing under operationally realistic conditions. Operations currently conducted at Port Adak would continue.

4.9.4.2 Alternatives 1, 2, and 3

Construction
Any construction or facility modification required to provide support to the SBX would occur in previously disturbed areas in accordance with Port Adak guidelines and regulations. Other than minor, short-term increase from the use of potentially hazardous materials such as paints, solvents, and fuels, no adverse effects to ongoing hazardous materials storage and handling are anticipated. The small increases in the amount of potentially hazardous materials used during construction activities would result in generation of added wastes. However, this increase is not expected to be significant and would be accommodated in accordance with existing Port Adak protocol and applicable state and federal regulations.

Operation
Increased operations that could take place at Port Adak would be servicing and maintenance of the SBX. Purchase and use of potentially hazardous materials associated with SBX operation and maintenance would be handled in accordance with ongoing materials management practices. Routine and preventative maintenance activities associated with the SBX would result in the generation of small quantities of potentially hazardous waste. The types of waste generated are not expected to dramatically differ from existing waste generated at the Port Adak, and these wastes would be handled in accordance with ongoing Port Adak procedures. SBX operation is not expected to significantly impact ongoing hazardous waste management or disposal practices.

4.9.4.3 Cumulative Impacts
The use of the required scheduling and coordination process and adherence to applicable Port Adak and APSC procedures and DoD directives concerning radar operations would preclude
the potential for significant incremental, additive cumulative impact to hazardous materials and waste management practices.

4.9.4.4 Mitigation Measures
No hazardous materials/hazardous materials management mitigation measures are proposed for GMD ETR activities at Port Adak.

4.9.5 HEALTH AND SAFETY—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PORT ADAK

4.9.5.1 No Action Alternative
Under the No Action Alternative, the GMD ETR would not be established, and interceptor and target launch scenarios would not require the SBX for testing under operationally realistic conditions. Operations currently conducted at Port Adak would continue.

4.9.5.2 Alternatives 1, 2, and 3

Construction
Any construction or facility modification required to support the SBX would occur in accordance with existing host installation safety protocol/plans and applicable state and federal requirements. No adverse effects to health and safety of construction contractors or the public are anticipated.

Operation
The SBX operating area would be in the vicinity of the mooring location at Finger Bay, as shown in figure 2.3.1-16. Configuration and general operation of the SBX would occur as described in section 2.1.4. The transmit/receive RF emission pattern would be mostly contained within a narrow main beam. The total duration of RF radiation per week would be approximately 5 to 6 hours.

An EMR/EMI survey and analysis would be conducted by the Joint Spectrum Center that considers HERP, HERF, and HERO. The survey is used in preparing a DD Form 1494 that would be required as part of the spectrum certification and frequency allocation process. The completed DD Form 1494 that has been processed and approved by the appropriate national and international authorities would be required prior to SBX testing.

The analysis provides recommendations for sector blanking and safety systems to minimize exposures. The proposed systems would have the appropriate safety exclusion zones established before operation, and warning lights to inform personnel when the system is in operation and emitting EMR. Mechanical and software stops would be used to prevent the main beam from being directed in specified sectors where it may present a hazard.

Potential health and safety impacts related to human exposure, EEDs, fuels, communications—electronics interference, and aircraft avionics would be similar to those described in section 4.3.5.2.5. Appendix G also provides summary information regarding potential SBX EMR issues.
The actual operating area of SBX at the mooring location would be restricted to minimize impacts. SBX operations would be coordinated with the FAA, Coast Guard and other groups or agencies as appropriate. Therefore, no health and safety impacts to coastal areas, airspace/aircraft or mariners are anticipated.

4.9.5.3 Cumulative Impacts
The concept of time averaging is important in consideration of the potential cumulative exposures that might occur near operating radars. Because tracking and search radar beams move rapidly, depending on the particular mission or exercise, it is unlikely that environmental exposures would ever consist of continuous, constant values of power density. Rather, almost universally, exposures would be intermittent and, when the radars are transmitting, the electromagnetic fields would be constantly changing in intensity. Thus, the potential for additive, incremental cumulative impacts from EMR exposure is extremely limited.

4.9.5.4 Mitigation Measures
Limitations imposed on the range of azimuth and angles of operation would preclude potential impacts related to health and safety. Mechanical and software stops would be used to control the radar’s operation.

4.9.6 UTILITIES—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PORT ADAK
A project may have substantial effects on infrastructure and utilities if it increases demand in excess of utility system capacity to the point that substantial expansion would be necessary. Environmental impacts could also result from system deterioration due to improper maintenance or extension of service beyond its useful life.

4.9.6.1 No Action Alternative
Under the No Action Alternative, the GMD ETR would not be established, and the SBX would not be developed to support interceptor and target launch scenarios, needed for operationally realistic test conditions. Port Adak would continue their current operations.

Energy
Daily average demand for electricity at the City of Adak is 1 MW. This is 6.9 percent of the maximum capacity of the electrical service, 14.5 MW.

Water
Potable water consumption at Adak is approximately 1.1 million liters (300,000 gallons) per day. This is 30 percent of the maximum available amount of potable water, 3.8 million liters (1 million gallons) per day.

Wastewater
Recent wastewater generation at Adak amounted to approximately 1 percent of the total water flow into Kuluk Bay, or 30,283 liters (8,000 gallons) per day.
Solid Waste
Solid waste disposal at Adak is handled by landfill and burning.

4.9.6.2 Alternatives 1, 2, and 3
All of the alternatives would include SBX as one of the components of the Proposed Action. The operation of SBX would require BOA and a PSB.

Electrical power requirements for the SBX platform and its various payloads would be approximately 21.8 MW, supplied by six on-board 3.64-MW generators. The SBX would be self-propelled by two of four steerable 3.4-MW electric thrusters that would effectively drive and maneuver the SBX without assistance. During transportation, these retractable, Z-drive thrusters would consume 7 MW, leaving 14.8 MW available for necessary ship-board operations, as well as the XBR.

The SBX has a fuel capacity of approximately 3,100,000 liters (818,000 gallons). The approximate fuel consumption for transit and radar operation is 54,800 liters (14,500 gallons) per day, which would only amount to only approximately 1.8 percent of total fuel capacity daily. Fuel consumption at the mooring site would be approximately 11,350 liters (3,000 gallons) per day.

There would be a total of 50 crew members, including 20 marine crew and 30 GMD mission support personnel. Additionally, up to 50 people could be accommodated on board on a temporary daytime basis.

At the intervals between GMD test missions, the SBX would return to a PSB or nearby mooring area for crew rotations, re-supply, and maintenance activities. While at an adjacent mooring location, only three of the generators would be used, one operating continually while in port for daily ship functions while the remainder would power the half- or fully populated radar 3 hours per day. A supply ship would deliver food, supplies, repair parts, and fuel from the PSB.

The latter scenario would apply at Port Adak. Although Adak piers do not offer adequate depth to accommodate the draft of the SBX, the vessel can potentially moor at nearby Finger Bay. A re-supply vessel could be required. Personnel would be ferried to the SBX each day either by watercraft or helicopter. There would be no direct impacts to area utilities from the self-contained SBX.

Should existing facilities at Port Adak be unavailable or inadequate at the PSB to accommodate approximately 25 personnel, construction of new, environmentally controlled storage and administration facilities would be necessary. A potential location for a new warehouse would be adjacent to Building 2310. Ongoing logistics and support operations such as re-supply, fueling and maintenance, and crew/operator training would also occur at the PSB.

Studies have shown an average 189 liters (50 gallons) per capita per day water consumption and 170 liters (45 gallons) per capita per day of wastewater production. Recent figures indicate that in the United States, the per capita generation of municipal solid waste in 1998 was 2 kilograms (4.46 pounds) per capita per day (U.S. Environmental Protection Agency, Region 9, 2002). Average daily demand for water, wastewater, and municipal solid waste for a maximum
25 personnel would be estimated as follows, based on typical usage: 4,725 liters (1,250 gallons) water, or 0.125 percent of current capacity; 4,258 liters (1,125 gallons) wastewater, or 0.125 percent of current capacity; and 50 kilograms (112 pounds) of solid waste. Any new facilities being constructed at Port Adak would be required to facilitate this level of use, as well as to accommodate any energy demand. Utilities at Adak were originally designed for a much larger population than that currently residing in the ROI since base closure took place. Consequently, current demand levels, as opposed to capacity, remain comparatively low and utilities systems would easily be able to accommodate the increased demand from SBX-related activities.

4.9.6.3 Cumulative Impacts
At this time, there are no ongoing or foreseeable future programs/plans identified in the ROI that when combined with the relatively minor SBX utility requirements would result in cumulative impacts to utilities. Therefore, no cumulative impacts are anticipated with Alternatives 1, 2, and 3.

4.9.6.4 Mitigation Measures
No utilities mitigation measures are proposed for GMD ETR activities at Adak.

4.9.7 VISUAL AND AESTHETIC RESOURCES—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PORT ADAK

4.9.7.1 No Action Alternative
Under the No Action Alternative, the SBX would not be located at Adak. There would be no alteration of the existing visual setting and the adjacent area. No significant impacts to visual and aesthetic resources would occur, and no mitigation measures are proposed.

4.9.7.2 Alternatives 1, 2, and 3
Visual resources could possibly be affected by the proposed SBX at Adak. The radar would be approximately 76 meters (250 feet) tall and the SBX platform would be 119 meters (390 feet) long and 73 meters (238 feet) wide. Potentially the SBX would be located at Adak intermittently over a period of 7 months per year.

In an effort to determine the existing visual quality of each of the SBX locations, the following method was modified from “Landscape Aesthetics: A Handbook for Scenery Management” (U.S. Department of Agriculture, U.S. Forest Service, 1995). The handbook outlines ways to measure individual aspects of visual resources and then rate the scenic value class of each of the locations. The following criteria were used to determine the scenic value class for the potential SBX locations: scenic attractiveness, viewer concern, and distance zones. Scenic attractiveness is the measure of scenic quality based on human perceptions of inherent beauty of the forms, colors, textures, and visual composition of an individual landscape. Viewer concern can be defined as the level of scenic importance based on expressed human concern for the scenic quality of land areas viewed. The distance zone is a principal indicator of scenic importance based on the distance an area can be seen by observers and the degree of visible detail within that zone. In addition, scenic integrity is included to determine the current level of modification to an area. A description of the scenic value rating criteria and scenic attractiveness can be found in appendix B.
Scenic Attractiveness
The potential mooring location for the SBX at Port Adak is within Finger Bay, where the viewing areas are considered to be typical (B) of the area.

Concern Level
Although the visual resources at Port Adak may be considered significant by some viewers, most of those affected would be associated with the port and would be accustomed to this type of activity. Therefore, the level of concern of the viewers would be considered to be low (Level 3).

Distance Zone
The SBX would be moored within the foreground (FG) view of the shoreline.

Scenic Value Class
The scenic value class for Port Adak as determined from the scenic value class table, table 4.9.7-1, would be moderate (3) due a lack of viewer concern and a typical level of scenic attractiveness.

Scenic Attractiveness
A – Distinctive, B – Typical, C – Indistinctive

Distance zone and Concern Level
FG1 – Foreground with a high level of concern
MG1 – Mid-ground with a high level of concern
BG1 – Background with a high level of sensitivity
FG2 – Foreground with a moderate level of sensitivity
MG2 – Mid-ground with a moderate level of sensitivity
BG2 – Background with a moderate level of sensitivity
FG3 – Foreground with a low level of sensitivity
MG3 – Mid-ground with a low level of sensitivity
BG3 – Background with a low level of sensitivity

Scenic Value Class
1-2: High public value.
3-5: Moderate public value.
6-7: Low public value.

Scenic Integrity
Alteration of the area has been greatly limited and the level of scenic integrity is currently considered to be “very high”, which means that the valued landscape is intact with only insignificant if any deviation or disturbance.

The potential mooring site is located within Finger Bay, which is separated from Adak by a small peninsula known as Lucky Point. This peninsula has an elevation of approximately 150 meters.
(492 feet), which would inhibit the view of the SBX from Adak. Also, due to weather conditions the visibility in Adak is typically limited to 1.6 kilometers (1 mile) horizontally, and the potential SBX mooring site is approximately 3.7 kilometers (2.3 miles) from Port Adak. These factors, along with a moderate scenic value and low viewer concern, would result in minimal adverse impacts to the visual resources at Adak.

4.9.7.3  Cumulative Impacts
The SBX would be moored temporarily and intermittently; therefore, cumulative impacts due to the SBX are not anticipated.

4.9.7.4  Mitigation Measures
No visual resources mitigation measures are proposed for GMD ETR activities at Adak.
4.10 PORT OF VALDEZ—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE

4.10.1 AIR QUALITY—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PORT OF VALDEZ

4.10.1.1 No Action Alternative

Under the No Action Alternative, the GMD ETR would not be established, and interceptor and target launch scenarios would not require the SBX for testing under operationally realistic conditions. Current air emission levels would remain the same, as listed in table 4.10.1-1. Operations currently conducted at the Port of Valdez would continue.

| Table 4.10.1-1: Summary of Emissions of Regulated Air Pollutants in the Port of Valdez |
|--------------------------------|-----------------------------|-----------------------------|-----------------------------|-----------------------------|-----------------------------|
|                                | PM-10 metric tons (tons)/year | Sulfur Dioxide metric tons (tons)/year | Carbon Monoxide metric tons (tons)/year | Nitrogen Dioxide metric tons (tons)/year | Volatile Organic Compounds metric tons (tons)/year |
| Valdez Marine Terminal         | 252.2 (278)                  | 1593.9 (1,757)               | 124.3 (137)                  | 1,431.5 (1,578)               | 3142.5 (3,464)               |
| Adjacent Facilitiesa           | 27.2 (30)                    | 116.1 (128)                  | NA                          | 100.7 (111)                   | NA                          |

Source: U.S. Department of the Interior, Bureau of Land Management, 2002b

a = Includes the Petro Star Refinery, the City of Valdez and the Valdez Airport
NA = Not Available

4.10.1.2 Alternatives 1, 2, and 3

Construction

Construction and facility modification required to provide support to the SBX would occur in previously disturbed areas. Construction activities would be conducted in accordance with all appropriate regulations and permits. Other than minor, short-term impacts from construction, no exceedances of the NAAQS or state AAQS would be anticipated.

Operation

Operational emissions aboard the SBX would be limited to the exhaust produced by generators and maintenance. Maintenance-related emissions would include minimal levels of volatile organic compound emissions that are not expected to have a significant impact on air quality.

65 Percent and Fully Populated SBX

Based on five tests per year the SBX would be at the Port of Valdez PSB for 7 months. For conservative analysis purposes, 9 months will be used. The SBX is being analyzed as a mobile source with an expected use of 6,600 hours per year (24 hours a day for 9 months). The SBX on-board power plant planned for use would include eight 3.64-MW diesel driven generators. While at the PSB, only three of the generators would be used. One would operate continually while in port for daily ship functions. The other two generators would be required for powering of the 65 percent or fully populated radar for 3 hours per day. This represents 6,600 hours of operation of one 3.64-MW generator and 1,650 hours (825 hours each) of operation for the other two generators that would be in operation at the PSB. Total power output for the three
3.64-MW generators would be 30,030 MW hours for the time the SBX is at the PSB. During the times the SBX is able to moor at the dock at Valdez, only two generators would be used for 3 hours per day to power the radar. The SBX would connect to shore power for normal ship functions. The SBX would not be considered a stationary source at the Port of Valdez; therefore, neither a Prevention of Significant Deterioration review nor a Title V permit would be required.

The remaining 3 months of the year it is expected the SBX would be in transit or at one of the SBX operating areas.

4.10.1.3 Cumulative Impacts
Other emission sources within the proposed ROI include the Valdez Marine Terminal, which is the largest emission producer in the area. The TAPS owners have recently completed an EIS for a 30-year continuation of an Agreement and Grant of Right-of-Way for the Trans-Alaska Pipeline, which includes the Valdez Marine Terminal. The analysis has determined that current and future levels of emissions at the Valdez Terminal would be within Alaska Department of Environmental Conservation operating permits. It is anticipated that the addition of emissions from the SBX in the vicinity of the Valdez Marine Terminal would not exceed NAAQS or AAQS levels.

4.10.1.4 Mitigation Measures
No air quality mitigation measures are proposed for GMD ETR activities.

4.10.2 AIRSPACE—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PORT OF VALDEZ

4.10.2.1 No Action Alternative
Under the No Action Alternative, the GMD ETR would not be established, and interceptor and target launch scenarios would not require the SBX for testing under operationally realistic conditions.

4.10.2.2 Alternatives 1, 2, and 3
The Proposed Action related to airspace would be full-power emissions from the SBX while at the mooring location south of Valdez in the Port of Valdez.

Operation
Controlled and Uncontrolled Airspace
Unrestricted operation of the SBX at the mooring location would have the potential to adversely affect air operations. As discussed in section 4.3.2.2.1, the SBX would not exceed military aircraft interference standards or the FAA standard for peak power levels. The SBX could exceed the 300 V/m average power threshold. The average power threshold is based upon reducing the time of exposure of aircraft avionics (electronic equipment) to High Intensity Radiated Fields in order to preclude shortening the life of the aircraft avionics. Therefore, the concern is not interference but is a reduction in life of the aircraft avionics. As shown in table 2.1.4-2, the fully populated radar has a potential for interference with aircraft (exceeding the
300 V/m average power threshold) out to a distance of 19 kilometers (11.8 miles) from the SBX.

In order to avoid or minimize adverse effects from EMR/EMI, DoD has established a coordination process with responsible agencies and airspace users. A full EMR/EMI survey and analysis would be conducted by the Joint Spectrum Center, in coordination with the FAA, and other potentially affected users. The survey is used in preparing a DD Form 1494 that would be required as part of the spectrum certification and frequency allocation process. The completed DD Form 1494 that has been processed and approved by the appropriate national and international authorities would be required prior to SBX testing.

The results of the survey would also be used to define the operating area for the SBX (acceptable azimuths and operating angles). The maximum operating area would be all azimuths (360 degrees), and all angles up to 90 degrees. The maximum potential interference distances are listed in table 2.1.4-2 and on figure 3.10.2-1.

The actual SBX operating area at the mooring location would be restricted in order to minimize impacts to aircraft operations, EEDs, and communication equipment. A high-energy radiation area notice would be published on the appropriate aeronautical charts, notifying aircraft of a RF radiation area. The boundaries of the SBX high-energy radiation area would be configured to minimize impacts to aircraft operations and other potentially affected systems. The establishment of this SBX high-energy radiation area would not impose any new flight restriction requirements.

SBX operations would be coordinated with the FAA and would be scheduled to occur during hours of minimal aircraft operations. Coordination with the Anchorage ARTCC would occur prior to and during each test. Consequently, there would be no reduction in the amount of navigable airspace, and thus no impacts to the controlled and uncontrolled airspace in the ROI would result.

Special Use Airspace
There is no special use airspace within the ROI. Consequently, there would be no impacts to special use airspace.

En Route Airways and Jet Routes
The two en route low altitude airways (A7, V 481), one high altitude jet route (J167), and two great circle routes from North America to the Far East (NCA 13 and NCA 20) would be considered in defining the SBX operating area. There are additional approach and departure routes for the Valdez Pioneer Airport that would also need to be considered when defining the SBX high energy radiation area. The SBX would be programmed to limit RF emissions in the direction of airways that pass within the potential interference distance. In addition, since the radar beam is in constant motion, should an aircraft enter the interference area, it is highly unlikely that the SBX would illuminate an aircraft long enough to affect the on-board electronics.

Airports and Airfields
Valdez Pioneer Airport is located approximately 12 kilometers (7.5 miles) northeast of the proposed mooring location. With the restrictions placed on the SBX in a manner similar to the
GBR-P radar at RTS, standard instrument approach and departure procedures at the airfield would continue unhindered. Existing airfield or airport arrival and departure traffic flows would also not be affected and access to the airfield would not be curtailed.

There are a number of air navigation facilities within the airspace ROI. However, they operate at lower frequencies (in the MHz range) than the X-band SBX, and would not normally experience any interference from the SBX. Nevertheless, there is the potential for interference from the grating (side) lobes and the main beam. Section 4.10.5 (Health and Safety) provides a detailed discussion of the potential for electronic communications (in-band and adjacent band) and harmonic band RF interference, as well as non-frequency-related interference (high-power effects).

Emissions from the SBX may also potentially degrade the overall system performance of in-band airborne and ship based systems such as fire control, bomb/navigation in military aircraft, and weather radars in both civilian and military aircraft, which all operate in the X-band (8 to 12 GHz). However, the SBX high-energy radiation area would be configured to minimize impacts to these airborne and ship-based systems.

4.10.2.3 Cumulative Impacts

Because the SBX operates in different frequency ranges than most aircraft radars, there would be limited potential for an incremental, additive cumulative electromagnetic effect upon the operation of an air navigation facility or the signal used by aircraft. Moreover, the frequency allocation operating permit process would take into consideration potential impacts on other resources in the region and would preclude the potential for cumulative impacts. The use of the required scheduling and coordination process, and adherence to applicable DoD directives concerning radar operations would also preclude the potential for significant incremental, additive, cumulative impacts.

No other projects in the airspace ROI have been identified that would have the potential for other incremental, additive cumulative impacts to controlled or uncontrolled airspace, special use airspace, en route airways and jet routes, or airfields and airports in the ROI.

4.10.2.4 Mitigation Measures

The actual SBX operating area at the mooring location would be restricted in order to minimize impacts to aircraft operations, EEDs, and communication equipment. In addition to charting the SBX high-energy radiation area notice, information would be published in the Airport Facility section of the FAA Airport Guide, and local NOTAMs would be issued to notify pilots of the high-energy radiation area. The boundaries of the SBX high-energy radiation area would be configured to minimize impacts to aircraft operations and other potentially affected systems. Additionally, flight service personnel would brief pilots flying in the vicinity about the SBX high-energy radiation area.
4.10.3 BIOLOGICAL RESOURCES—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PORT OF VALDEZ

4.10.3.1 No Action Alternative

Under the No Action Alternative, the GMD ETR would not be established, and interceptor and target launch scenarios would not require the SBX for testing under operationally realistic conditions. Operations currently conducted at the Port of Valdez would continue.

4.10.3.2 Alternatives 1, 2, and 3

Construction

Any construction or facility modification required to provide support to the SBX would occur in previously disturbed areas in accordance with host installation guidelines and regulations. Other than minor, short-term impacts from noise, such as startling and temporary displacement, no adverse effects to biological resources are anticipated.

Operation

Impacts to biological resources from operation of the SBX at the Port of Valdez would be similar to those described above in sections 4.3.3.3 and 4.6.3.2. The SBX vessel would incorporate marine pollution control devices such as keeping decks clear of debris, cleaning spills and residues, and engaging in spill and pollution prevention practices in compliance with the UNDS provisions of the Clean Water Act. No significant long-term adverse impacts are anticipated to Essential Fish Habitat, area seabirds and water fowl, or widely distributed, open-water species such as humpback, killer, and minke whales, sea otters, Steller sea lions, harbor seals, and Dall and harbor porpoises that occur in Prince William Sound.

4.10.3.3 Cumulative Impacts

No other projects in the ROI have been identified that would have the potential for incremental, additive cumulative impacts to biological resources in the ROI. As stated above, no effects are anticipated on whales, other marine mammals, or birds that might be present in the vicinity of the homeport and transit locations.

4.10.3.4 Mitigation Measures

No biological resources mitigation measures are proposed for GMD ETR activities at the Port of Valdez.

4.10.4 HAZARDOUS MATERIALS AND HAZARDOUS WASTE—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PORT OF VALDEZ

4.10.4.1 No Action Alternative

Under the No Action Alternative, the GMD ETR would not be established, and interceptor and target launch scenarios would not require the SBX for testing under operationally realistic conditions. Operations currently conducted at the Port of Valdez would continue.
4.10.4.2 Alternatives 1, 2, and 3

Construction
Any construction or facility modification required to provide support to the SBX would occur in previously disturbed areas in accordance with host installation guidelines and regulations. Other than minor, short-term increase from the use of potentially hazardous materials such as paints, solvents and fuels, no adverse effects to ongoing hazardous materials storage and handling are anticipated. The small increases in the amount of potentially hazardous materials used during construction activities would result in generation of added wastes. However, this increase is not expected to be significant and would be accommodated in accordance with existing APSC protocol and applicable state and federal regulations.

Operation
Increased operations that could take place at the Port of Valdez would be servicing and maintenance of the SBX. Purchase and use of potentially hazardous materials associated with SBX operation and maintenance would be controlled within the APSC HAZCORE system. Recycling and reuse of spent and excess materials can be expected to maintain the level of hazardous material usage at or near current conditions. Routine and preventative maintenance activities associated with the SBX would result in the generation of small quantities of potentially hazardous waste. The quantity of waste generated would not change the port’s generator status. The types of waste generated are not expected to dramatically change. Wastes would be handled in accordance with TAPS Environmental Protection Manual, EN-43-2 procedures. SBX operation is not expected to significantly impact ongoing hazardous waste management or disposal practices.

4.10.4.3 Cumulative Impacts
The use of the required scheduling and coordination process and adherence to applicable Port and APSC procedures and DoD directives concerning radar operations would preclude the potential for significant incremental, additive cumulative impact to hazardous materials and waste management practices.

4.10.4.4 Mitigation Measures
No hazardous materials/hazardous waste management mitigation measures are proposed for GMD ETR activities at the Port of Valdez.

4.10.5 HEALTH AND SAFETY—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PORT OF VALDEZ

4.10.5.1 No Action Alternative
Under the No Action Alternative, the GMD ETR would not be established and interceptor and target launch scenarios would not require the SBX for testing under operationally realistic conditions. Operations currently conducted at the Port of Valdez would continue.
4.10.5.2 Alternatives 1, 2, and 3

Construction

Any construction or facility modification required to support the SBX would occur in accordance with existing host installation safety protocol/plans and applicable state and federal requirements. No adverse effects to health and safety of construction contractors or the public are anticipated.

Operation

The SBX operating area would be in the vicinity of the mooring location in the Port of Valdez, as shown in figure 2.3.1-17. Configuration and general operation of the SBX would occur as described in section 2.1.4. The transmit/receive RF emission pattern would be mostly contained within a narrow main beam. The total duration of RF radiation per week would be approximately 5 to 6 hours.

An EMR/EMI survey and analysis would be conducted by the Joint Spectrum Center that considers HERP, HERF, and HERO. The survey is used in preparing a DD Form 1494 that would be required as part of the spectrum certification and frequency allocation process. The completed DD Form 1494 that has been processed and approved by the appropriate national and international authorities would be required prior to SBX testing.

The analysis provides recommendations for sector blanking and safety systems to minimize exposures. The proposed systems would have the appropriate safety exclusion zones established before operation, and warning lights to inform personnel when the system is in operation and emitting EMR. Mechanical and software stops would be used to prevent the main beam from being directed in specified sectors where it may present a hazard.

Potential health and safety impacts related to human exposure, EEDs, fuels, communications—electronics interference, and aircraft avionics would be similar to those described in section 4.3.5.2.5. Appendix G also provides summary information regarding potential SBX EMR issues.

The actual operating area of SBX at the mooring location would be restricted to minimize impacts. SBX operations would be coordinated with the FAA, Coast Guard and other groups or agencies as appropriate. Therefore, no health and safety impacts to coastal areas, airspace/aircraft or mariners are anticipated.

4.10.5.3 Cumulative Impacts

The concept of time averaging is important in consideration of the potential cumulative exposures that might occur near operating radars. Because tracking and search radar beams move rapidly, depending on the particular mission or exercise, it is unlikely that environmental exposures would ever consist of continuous, constant values of power density. Rather, almost universally, exposures would be intermittent and, when the radars are transmitting, the electromagnetic fields would be constantly changing in intensity. Thus, the potential for additive, incremental cumulative impacts from EMR exposure is extremely limited.
4.10.5.4 Mitigation Measures

Limitations imposed on the range of azimuth and angles of operation would preclude potential impacts related to health and safety. Mechanical and software stops would be used to control the radar's operation.

4.10.6 TRANSPORTATION—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PORT OF VALDEZ

4.10.6.1 No Action Alternative

Under the No Action Alternative, the GMD ETR would not be established, and interceptor and target launch scenarios would not require the SBX for testing under operationally realistic conditions. Operations currently conducted at the Port of Valdez would continue.

4.10.6.2 Alternatives 1, 2, and 3

Construction

Any construction or facility modification required to provide support to the SBX would occur in previously disturbed areas, such as the Container Dock staging area or the “Old Town” area, in accordance with guidelines and regulations. No adverse effects to transportation resources are anticipated.

Operation

The SBX would be required to meet environmental requirements for commercial vessels.

At the Port of Valdez, the City Dock is incapable of accommodating either cruise ships or the SBX, although the City of Valdez is upgrading this dock to allow its usage by the former. At high tide, the nearby North Pacific Fuel Dock is deep enough to accommodate the SBX. At the Container Dock, pier-side operations could be carried out in areas wherein depths exceed 15.2 meters (50 feet).

Pier space would not be available year-round at the Container Dock, however, as the space would be yielded to cruise shipping during the May-September tourism season. Other activities at the Container Dock could also interfere with the SBX potential for utilizing it, including occasional barge use. However, there are mooring locations near the Container Dock and across the port near the terminus of the Alaska Pipeline.

A security area or restricted area could be required for the mooring location at Valdez and would require coordination with the U.S. Army Corps of Engineers; a secure area currently exists near the oil tanker site. An Alaska Department of Natural Resources permit would be required for all actions within 4.8 kilometers (3 miles) of the shoreline, including mooring sites. Once underway, the SBX security zone would be similar to the Navy vessel protection zone that applies to Navy vessels that are underway. This moving zone includes a 91.4-meter (100-yard) security exclusion zone around the vessel and a slow speed zone between 91.4 and 457 meters (100 and 500 yards) from the vessel.
Coordination with local Native American groups such as the Tatitlek would be necessary to prevent any impacts to native fishing areas, particularly during the August salmon run and during other peak fishing seasons (such as halibut). Mooring locations would also be required to avoid the area wherein two major communication cables are located.

Transit to and from Prince William Sound could necessitate the use of at least two tugs for assistance. In addition, the Ship Escort and Response Vessel System provides emergency responders to escort ships in and out of the Port of Valdez.

Coordination would be required with the U.S. Coast Guard to lessen requirements for channel (Valdez Narrows) closure and preclude potential delays of oil tankers utilizing the area, as well as to establish any required security zone. Completion of a vessel response plan, to be approved by the U.S. Coast Guard, could be required.

Some 20 people would be instated at the PSB. As many as 50 personnel could leave the SBX for onshore activities. Assuming a maximum of 50 automobile trips per day, this level would be an approximate 0.9-percent increase over the minimum current AADT level at MP3 on Richardson Highway at Valdez of 5,540 vehicles. No impacts to area roadways are expected.

4.10.6.3 Cumulative Impacts
No other projects in the ROI have been identified that would have the potential for incremental, additive cumulative impacts to transportation resources in the ROI.

4.10.6.4 Mitigation Measures
No transportation mitigation measures are proposed for GMD ETR activities at the Port of Valdez.

4.10.7 UTILITIES—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PORT OF VALDEZ

4.10.7.1 No Action Alternative
Under the No Action Alternative, the GMD ETR would not be established and the SBX would not be developed to support interceptor and target launch scenarios, needed for operationally realistic test conditions. The Port of Valdez would continue its current operations.

Energy
Daily availability of electricity for Valdez via Copper Valley Electric Association is 13 MW, with 9.25 MW of backup power through its diesel station.

Water
Potable water hookups at Port of Valdez allow for demands exceeding approximately 245,185 liters (64,771 gallons).
Wastewater
Recent wastewater generation at the City of Valdez amounted to approximately 3.3 million liters (0.87 million gallons) per day. This amounts to 69.6 percent of the processing capacity of the City of Valdez Wastewater Treatment Plant over 4.73 million liters (1.25 million gallons) per day.

Solid Waste
Solid waste disposal at Port of Valdez is handled by private contractor.

4.10.7.2 Alternatives 1, 2, and 3
All of the alternatives would include SBX as one of the component of the Proposed Action. Electrical power requirements for the SBX platform and its various payloads would be approximately 21.8 MW, supplied by six on-board 3.64-MW generators. The SBX would be self-propelled by two of four steerable 3.4-MW electric thrusters that would effectively drive and maneuver the SBX without assistance. During transportation, these retractable, Z-drive thrusters would consume approximately 7 MW, leaving 14.8 MW available for necessary shipboard operations, as well as the XBR.

The SBX has a fuel capacity of approximately 3,100,000 liters (818,000 gallons). The approximate fuel consumption for transit and radar operation is 54,800 liters (14,500 gallons) per day, which would only amount to approximately 1.8 percent of total fuel capacity daily. Fuel consumption at the mooring site would be approximately 11,350 liters (3,000 gallons) per day.

There would be a total of 50 crew members, including 20 marine crew and 30 GMD mission support personnel. Additionally, up to 50 people could be accommodated on board on a temporary daytime basis.

At the intervals between GMD test missions, the SBX would return to a PSB or nearby mooring location for crew rotations, re-supply, and maintenance activities. While at an adjacent mooring location, only three of the generators would be used, one operating continually while in port for daily ship functions while the remainder would power the half- or fully populated radar three hours per day. A supply ship would deliver food, supplies, repair parts, and fuel from the PSB.

Valdez cannot commit to year-round pier space year for the SBX, but allows for numerous mooring locations near the container dock which would suffice for project operations. Thus a re-supply vessel would probably not be required. If the use of power hookups were deemed necessary for basic on-board ship activities, they would have to be constructed, as there are no hookups currently available at the docks. The power plant serving Valdez is well below capacity and could allow for the limited demands of the otherwise self-contained SBX. Potable water levels at the port are capable of sustaining large cruise ships and would likewise accommodate the SBX demands. Wastewater and solid waste needs would be handled by existing services, which charge on a per truck (wastewater) and per dumpster (solid waste) basis. Such services would be considered routine and would pose no impacts to port infrastructure; construction of power hookups would actually have a positive impact.

A new environmentally controlled warehouse would potentially be required for SBX operations to accommodate a maximum 25 personnel. Ongoing logistics and support operations such as re-supply, fueling/maintenance and crew/operator training would also occur at the PSB.
Studies have shown an average 189 liters (50 gallons) per capita per day water consumption and 170 liters (45 gallons) per capita per day of wastewater production. Recent figures indicate that in the United States, the per capita generation of municipal solid waste in 1998 was 2 kilograms (4.46 pounds) per capita per day (U.S. Environmental Protection Agency, Region 9, 2002). Average daily demand for water, wastewater, and municipal solid waste for a maximum 25 personnel would be estimated as follows, based on typical usage: 4,725 liters (1,250 gallons) water, 4,258 liters (1,125 gallons) wastewater and 50 kilograms (112 pounds) of solid waste. Any new facilities being constructed would be required to facilitate this level of use, as well as to accommodate any energy demand.

4.10.7.3 Cumulative Impacts

At this time, there are no ongoing or foreseeable future programs/plans identified in the region of influence that when combined with the relatively minor SBX utility requirements would result in cumulative impacts to utilities. Therefore, no cumulative impacts are anticipated with Alternatives 1, 2, and 3.

4.10.7.4 Mitigation Measures

No significant impacts would be anticipated with Alternatives 1, 2, and 3; therefore, no mitigation measures would be required or proposed.

4.10.8 VISUAL AND AESTHETIC RESOURCES—SEA-BASED TEST X-BAND RADAR PRIMARY SUPPORT BASE, PORT OF VALDEZ

4.10.8.1 No Action Alternative

Under the No Action Alternative, the SBX would not be located at Valdez. There would be no alteration of the existing visual setting and the adjacent area. No significant impacts to visual and aesthetic resources would occur, and no mitigation measures are proposed.

4.10.8.2 Alternatives 1, 2, and 3

Visual resources could possibly be affected by the proposed SBX at Valdez. The SBX would be approximately 76 meters (250 feet) tall, and the SBX platform would be 119 meters (390 feet) long and 73 meters (238 feet) wide. The SBX would be located at Valdez intermittently for approximately 7 months per year. The remaining 5 months of the year it is expected the SBX would be in transit or at one of the SBX operating areas.

In an effort to determine the existing visual quality of each of the SBX locations, the following method was modified from “Landscape Aesthetics: A Handbook for Scenery Management” (U.S. Department of Agriculture, U.S. Forest Service, 1995). The handbook outlines ways to measure individual aspects of visual resources and then rate the scenic value class of each of the locations. The following criteria were used to determine the scenic value class for the potential SBX locations: scenic attractiveness, viewer concern, and distance zones. Scenic attractiveness is the measure of scenic quality based on human perceptions of inherent beauty of the forms, colors, textures, and visual composition of an individual landscape. Viewer concern can be defined as the level of scenic importance based on expressed human concern for the scenic quality of land areas viewed. The distance zone is a principal indicator of scenic importance based on the distance an area can be seen by observers, and the degree of visible detail within that zone. In addition, scenic integrity is included to determine the current level of
Scenic Attractiveness

The scenic attractiveness of the Port of Valdez is considered to be distinctive (A) due to the surrounding mountain ranges which provide an outstanding visual quality unique to the Valdez area.

Concern Level

The level of concern for the viewers within the Port of Valdez can potentially be high (Level 1) due to recreational and tourist areas.

Distance Zone

The SBX would either be moored at a selected dock or at mooring locations across the port. These locations would potentially result in a foreground (FG) view from the docks, a mid-ground (MG) view from Valdez itself, or a background (BG) view from some of the residential areas.

Scenic Value Class

The scenic value class for the Port of Valdez as determined from the scenic value class table, table 4.10.8-1, would be high (1) for the foreground, mid-ground, and background areas of the ROI, due to the level of scenic attractiveness of the area.

Table 4.10.8-1: Scenic Value Class Determined for the Port of Valdez

Scenic Value Class

1-2: High public value.
3-5: Moderate public value.
6-7: Low public value.
Scenic Integrity

The scenic integrity for the SBX locations at the Port of Valdez could either be considered “very low,” which means that the area appears heavily altered, or “very high,” which means that the valued landscape is intact with only insignificant if any deviation or disturbance, depending on the view. The mountain ranges surrounding Valdez would particularly be classified as having a “very high” level of scenic integrity.

The size of a midsize oil tanker is approximately 305 meters (1,000 feet) long and 61 meters (200 feet) wide. Because Valdez is the site of the terminus of the Trans-Alaska Pipeline, numerous oil tankers are consistently entering Prince William Sound, which would limit the impacts to visual resources caused by the SBX. However, adverse impacts to visual resources could occur due to a certain amount of sensitive viewers and a high amount of scenic integrity depending on the viewpoint.

4.10.8.3 Cumulative Impacts

The SBX would be moored temporarily and intermittently; therefore, cumulative impacts due to the SBX are not anticipated.

4.10.8.4 Mitigation Measures

No visual resources mitigation measures are proposed for GMD ETR activities at the Port of Valdez.
4.11 BROAD OCEAN AREA

This section describes the potential impacts within the BOA that may occur as a result of the GMD ETR activities. The BOA includes those areas that are outside the U.S. territorial waters, and as such this section of the document complies with Executive Order 12114, *Environmental Effects Abroad of Major Federal Activities*. The information contained in this section is summarized from the *Theater Missile Defense Extended Test Range Supplemental Environmental Impact Statement* (U.S. Department of the Air Force, 1998), *PMRF Enhanced Capability Environmental Impact Statement* (Pacific Missile Range Facility, Barking Sands, 1998), *North Pacific Targets Program Environmental Assessment* (U.S. Army Space and Missile Defense Command, 2001b), and the *Development and Demonstration of the Long Range Air-Launch Target Environmental Assessment* (U.S. Department of Defense, 2002). These documents included environmental analysis of potential impacts from missile launches and other military actions in the Gulf of Mexico and the Central and North Pacific. As appropriate, additional information used to develop this section is referenced accordingly.

Airspace, biological resources, health and safety, and transportation were identified as resource areas with potential impacts in the BOA. Water quality and noise are included in the analysis, from the standpoint of potential impacts on marine life.

With the BOA being the ROI, there is no potential for impacts to cultural resources, land use, soils, and groundwater. Similarly, since the BOA is well removed from islands and population centers, no impacts to the human noise environment, socioeconomics, and utilities are anticipated. Impacts to air quality from similar missiles have been determined to be insignificant.

4.11.1 AIRSPACE—BROAD OCEAN AREA

4.11.1.1 Gulf of Mexico

**No Action Alternative**

Under the No Action Alternative, the SBX would not be developed, and the proposed SBX test activities in the Gulf of Mexico would not take place.

**Proposed Action**

The Gulf of Mexico ROI is defined as the overwater area that would be potentially affected by the Proposed Action using portions of the international airspace over the Gulf of Mexico. This includes the entire northern Gulf of Mexico within the Houston, Jacksonville, and Miami ARTCCs, and the Houston and Miami Oceanic CTA/FIR. The Proposed Action in the Gulf of Mexico would include sea trials of the SBX platform and full power testing of the SBX. The location of testing has not been determined; however, full power radar testing would be conducted in areas that would minimize impacts to airspace.

A full EMR/EMI survey and analysis would be conducted by the Joint Spectrum Center, in coordination with the FAA, DOT, and other potentially affected users. The survey is used in preparing a DD Form 1494 that would be required as part of the spectrum certification and frequency allocation process. The completed DD Form 1494 that has been processed and approved by the appropriate national and international authorities would be required before SBX testing.
The results of the survey would also be used to define the operating area for the SBX (acceptable azimuths and operating angles). The maximum operating area would be all azimuths (360 degrees), and all angles up to 90 degrees. Table 2.1.4-2 lists the maximum potential interference distances.

**Special Use Airspace**

Full power radar testing would be planned to take place within existing special use airspace such as warning areas, and under conditions controlled to eliminate hazards to non-participating aircraft. Coordination with the FAA would be required before testing.

**En Route Airways and Jet Routes**

Full power radar testing would be planned to take place in an area that would minimize potential impacts to en route airways and jet routes. The specific testing location would be coordinated with the FAA to avoid en route airways and jet routes. By avoiding these routes, the proposed activities would not require a change to an existing or planned IFR minimum flight altitude, a published or special instrument procedure, or an IFR departure procedure; nor would they require a change to a VFR operation from a regular flight course or altitude. The SBX would be programmed to limit RF emissions in the direction of airways that pass within the potential interference distance. In addition, since the radar beam is in constant motion, should an aircraft enter the interference area, it is highly unlikely that the SBX would illuminate an aircraft long enough to affect the on-board electronics. Consequently, no impacts to the surrounding low altitude airways or high altitude jet routes would occur from SBX testing.

**4.11.1.2 En Route Gulf of Mexico to Pacific Ocean**

**No Action Alternative**

Under the No Action Alternative, the GMD ETR would not be developed, and the proposed transit of the SBX from the Gulf of Mexico to the Pacific Ocean would not take place.

**Proposed Action**

The en route ROI is defined as the overwater area that would be potentially affected by the Proposed Action using portions of the international airspace along the route from the Gulf of Mexico to the Pacific Ocean. The Proposed Action would include transit and testing of the SBX to include full power testing of the SBX. The location of testing has not been determined; however, full power radar testing would be conducted in areas that would minimize impacts to airspace.

As described in the previous section, an EMR/EMI survey and analysis and DD Form 1494 would be required as part of the spectrum certification and frequency allocation process. A completed DD Form 1494 that has been processed and approved by the appropriate national and international authorities would be required before SBX testing.

Potential impacts to en route airways and special use airspace would be minimal and similar to those described for the Gulf of Mexico.
4.11.1.3 Pacific Ocean

No Action Alternative

Under the No Action alternative, the GMD ETR would not be developed, and the proposed full range of GMD flight test activities in the Pacific BOA would not take place. Ongoing missile flight test activities would continue to use the existing special use airspace and other areas in the Pacific BOA. The continuing activities would not conflict with any airspace use plans, policies, and controls.

Proposed Action

The Pacific BOA ROI is defined as the overwater area that would be potentially affected by the Proposed Action using portions of the international airspace over the Pacific Ocean. This includes the entire northern Pacific BOA within the Oakland and Anchorage ARTCCs Oceanic CTA/FIR. The Proposed Action in the Pacific BOA would include missile booster drop zones, missile intercepts, and intercept debris. In addition, the launching of mobile sea launch targets and air launch targets could have airspace use impacts that would be essentially the same as the ground-launched missiles.

The Proposed Action would also include transit of the SBX from a PSB to the appropriate SBX performance region, SBX operations within the performance region in support of GMD flight tests, and transit back to a PSB.

Controlled and Uncontrolled Airspace

The airspace in the ROI outside territorial limits lies in international airspace and, consequently, is not part of the NAS. Because the area is in international airspace, the procedures of ICAO, outlined in ICAO Document 444, *Rules of the Air and Air Traffic Services*, are followed. ICAO Document 444 is the equivalent air traffic control manual to FAA Handbook 7110.65, *Air Traffic Control*. The FAA acts as the U.S. agent for aeronautical information to the ICAO, and air traffic in the overwater ROI is managed by the Honolulu, Oakland, and Anchorage ARTCCs.

After launch, typically the GBI and target missiles would be above 18,290 meters (60,000 feet) within seconds of launch. As such, all other local flight activities would occur at sufficient distance and altitude that the target missile and GBI missiles would be little noticed. However, activation of stationary Altitude Reservation (ALTRV) procedures, where the FAA provides separation between non-participating aircraft and the missile flight test activities, would impact the controlled airspace available for use by non-participating aircraft for the duration of the ALTRV, usually for a matter of a few hours, with a backup day reserved for the same hours. Because the airspace in most of the intercept debris areas is not heavily used by commercial aircraft, and is far removed from the en route airways and jet routes crossing the North Pacific, the impacts to controlled/uncontrolled airspace would be minimal.

However, the intercept scenarios with targets from KLC and GBIs from Vandenberg AFB (figure 2.1.8-3) may have moderate impacts to airspace due to the potential impacts from intercept debris. It has been determined that intercept debris as small as 1 gram could cause significant damage to a commercial aircraft traveling at cruising speed and altitude. The probability of fatality for a 737 aircraft flying through a target missile debris cloud is depicted in figure 4.11.1-1. The figure shows the debris cloud to be approximately 35 kilometers (22 miles) in diameter, and the area
Probability of Fatality Per Cell for 737 (Model Representative Output)

EXPLANATION

- $1.014 \times 10^{-8}$
- $7.411 \times 10^{-5}$
- $1.482 \times 10^{-4}$
- $2.223 \times 10^{-4}$
- $2.964 \times 10^{-4}$

Figure 4.11.1-1

GMD ETR Final EIS
where the probability of fatality is greater than 1 in 1 million is approximately 22 kilometers (13.6 miles) in diameter. This area of higher risk would need to be avoided by all aircraft. The time for the intercept debris to pass through commercial airspace cruising altitudes is approximately 3 hours after the intercept. All en route airways and jet routes that are predicted to pass through the target missile or GBI missile intercept debris areas would need to be identified before a test to allow sufficient coordination with the FAA to determine if the aircraft on those routes would be affected, and if so, if they would need to be re-routed or rescheduled. Routing around the debris areas would be handled in a manner similar to severe weather. The additional time for commercial aircraft to avoid the area would generally be less than 10 minutes at cruising altitudes and speeds.

For sea-launch target launches, it may be necessary to establish a 3.7-kilometer (2-nautical-mile) radius temporary Warning Area, extending from the surface up to 18,290 meters (60,000 feet) mean sea level above the sea-launch platform. Such a restricted area would marginally reduce the amount of navigable airspace in the BOA ROI, but because the airspace is not heavily used by commercial aircraft and is far removed from the en route airways and jet routes crossing the North Pacific, the impacts to controlled and uncontrolled airspace would be minimal.

As described in the section 4.11.1.1, an EMR/EMI survey and analysis and DD Form 1494 would be required as part of the spectrum certification and frequency allocation process. A completed DD Form 1494 that has been processed and approved by the appropriate national and international authorities would be required before SBX operations in the Pacific Ocean. The spectrum certification process would identify coordination requirements that would be followed by the SBX for all operations.

Special Use Airspace
GMD ETR missile intercepts and intercept debris would generally occur outside special use airspace areas. As such, the Proposed Action would not represent a direct special use airspace impact. Similarly, the use of ALTRV procedures as authorized by the Central Altitude Reservation Function, an air traffic service facility, or appropriate ARTCC (in this case, the Oakland ARTCC) for airspace utilization under prescribed conditions would not impact special use airspace. According to the FAA Handbook, 7610.44, ALTRVs may encompass certain rocket and missile activities and other special operations as may be authorized by FAA approval procedures.

The primary responsible test range would coordinate with the Oakland ARTCC military operations specialist assigned to handle such matters and the airspace coordinator at the Honolulu Center or other appropriate Radar Approach Center using ALTRV request procedures. After receiving the proper information on each test flight, a hazard pattern would be constructed and superimposed on a chart depicting the area of operations. Ensuring that the hazard pattern would not encroach on any land mass, this area is then plotted using minimum points (latitude-longitude) to form a rectangular area. This plotted area is then faxed to the military operations specialist at Oakland ARTCC requesting airspace with the following information: area point (latitude-longitude); date and time for primary and backup (month, day, year, zulu time); and altitude. A copy would be sent to the Honolulu Center or other appropriate Radar Approach Center. A follow-up phone call would be made after 48 hours to verify receipt of the fax. When approval of the request of the airspace is received from the military operations specialist at
Oakland ARTCC, the primary responsible test range would submit an ALTRV request to Central Altitude Reservation Function who publishes the ALTRV 72 hours before the flight test.

Full power radar testing would generally not take place within existing special use airspace such as warning areas. However, operations would be conducted in coordination with the FAA to minimize potential hazard to non-participating aircraft.

**En Route Airways and Jet Routes**

The numerous airways and jet routes that crisscross the Pacific BOA airspace use ROI have the potential to be affected by the Proposed Action. However, target and GBI missile launches and missile intercepts would be conducted in compliance with DoD Directive 4540.1 that specifies procedures for conducting missile and projectile firing; namely, “firing areas shall be selected so that trajectories are clear of established oceanic air routes or areas of known surface or air activity” (DoD Directive 4540.1, E5, 1981).

Before conducting a missile launch and/or intercept test, NOTAMs would be sent in accordance with the conditions of the directive specified in the primary responsible test range requirements. In addition, to satisfy airspace safety requirements, the responsible test range would obtain approval from the Administrator, FAA, through the appropriate DoD airspace representative. Provision is made for surveillance of the affected airspace either by radar or patrol aircraft. In addition, safety regulations dictate that hazardous operations would be suspended when it is known that any non-participating aircraft have entered any part of the danger zone until the non-participating entrant has left the area or a thorough check of the suspected area has been performed.

In addition to the reasons cited above, minimal adverse impacts to the en route airways and jet routes are identified because of the required coordination with the FAA. Schedules are provided to the appropriate FAA facility (Honolulu, Anchorage, and Oakland ARTCCs) as agreed between the agencies involved. Aircraft transiting the open ocean ROI on one of the low-altitude airways and/or high-altitude jet routes that would be affected by flight test activities would be notified of any necessary rerouting before departing their originating airport and would therefore be able to take on additional fuel before takeoff. Real-time airspace management involves the release of airspace to the FAA when the airspace is not in use or when extraordinary events occur that require drastic action, such as weather requiring additional airspace.

The FAA ARTCCs are responsible for air traffic flow control or management to transition air traffic. The ARTCCs provide separation services to aircraft operating on IFR flight plans and principally during the en route phases of the flight. They also provide traffic and weather advisories to airborne aircraft. By appropriately containing hazardous military activities by using ALTRV procedures, non-participating traffic are advised or separated accordingly, thus avoiding substantial adverse impacts to the low altitude airways and high altitude jet routes in the ROI.

If a 3.7-kilometer (2-nautical-mile) radius temporary Warning Area, extending from the surface to 18,200 meters (60,000 feet) mean sea level, is proposed over the sea-launch platform, it would not have an impact on the en route airways and jet routes in Pacific BOA. The sea-launch platform would be positioned to avoid the en route airways and jet routes that cross the North Pacific.
SBX operating areas include several air routes as shown on figure 4.11.1-2. As described in section 4.11.1.1, an EMR/EMI survey and analysis and DD Form 1494 would be required as part of the spectrum certification and frequency allocation process. A completed DD Form 1494 that has been processed and approved by the appropriate national and international authorities would be required before SBX operations in the Pacific Ocean. The spectrum certification process would identify coordination requirements that would be followed by the SBX for all operations. The SBX would generally be able to operate from a location within the SBX performance region that does not interfere with the air routes that cross the region. The specific testing location would be coordinated with the FAA to avoid en route airways and jet routes. If the SBX were to operate in an air route location, non-participating aircraft could be routed around the SBX operating area. Such a diversion would generally be less than 20 kilometers (12.4 miles), a minor distance for the routes being flown.

Cumulative Impacts
GMD testing would request clearance of various areas of airspace and may cause rerouting or rescheduling of flights for periods of as much as 3 to 4 hours, five times a year. This could result in as much as 20 hours of direct effect on air traffic access per year. However, most impacts would be in remote areas that would have little effect on air traffic. Other missile test programs could also have similar, minor impacts in the same areas.

Therefore, GMD flight tests with intercepts in the vicinity of en route airways and jet routes, when combined with other missile test programs, could lead to cumulative impacts to airspace in the form of flight delays. The required scheduling process for the use of airspace would help to minimize these potential adverse cumulative impacts.

Mitigations Considered
Coordination with the FAA, scheduling GMD flight tests during hours of low aircraft traffic, and the implementation of positive air traffic control are the primary practices employed to avoid impacts to airspace. Therefore additional airspace mitigation measures are not proposed for GMD ETR activities in the BOA.

4.11.2 BIOLOGICAL RESOURCES—BROAD OCEAN AREA
Potential impacts of construction, building modification, and missile launches on terrestrial and marine biological resources within the Gulf of Mexico and open ocean ROI were addressed in detail in the Theater Missile Defense ETR Supplemental EIS-Eglin Gulf Test Range (U.S. Department of the Air Force, 1998), PMRF Enhanced Capability EIS (Pacific Missile Range Facility, Barking Sands, 1998), USAKA EIS (U.S. Army Strategic Defense Command, 1989a), USAKA Supplemental EIS (U.S. Army Space and Strategic Defense Command, 1993a), Theater Missile Defense Extended Test Range EIS (U.S. Army Space and Strategic Defense Command, 1994), and Kwajalein Atoll Temporary ETR EA (U.S. Army Space and Strategic Defense Command, 1995). The finding of these studies are incorporated by reference and summarized in the following sections. Based on the prior analysis done and the effects of past interceptor and target launch activities, the potential impacts of activities related to missile test flights on biological resources are expected to be minimal, as discussed below. Dual GBI and target missile launches could potentially occur. Impacts from these dual launches would in some cases be slightly greater than, but similar to, those analyzed below for single launches.
High Altitude Air Routes with Potential SBX Performance Regions

EXPLANATION
- High Altitude Air Routes
- SBX Performance Regions

Scale
- 0 571 kilometers
- 0 355 miles

Figure 4.11.1-2
4.11.2.1 Gulf of Mexico

As described in section 4.6.3.2, in terms of the potential for EMR impacts to wildlife, the power densities emitted from the SBX are unlikely to cause any biological effects in marine animals or birds.

4.11.2.2 En Route Gulf of Mexico to Pacific Ocean

Existing shipping routes would be used along the coast of South America to move the SBX from the Gulf of Mexico to the Pacific Ocean. The potential for impacts to marine mammals due to an accidental release of diesel fuel is considered low. There is evidence that dolphins can identify the presence of diesel fuel and lubricating oil and avoid it (U.S. Department of the Navy, 2001). The relatively slow speed of the SBX platform would preclude the potential for collision with a free-swimming marine mammal. Overall, no adverse impacts to marine mammals or other biological resources are anticipated.

4.11.2.3 Pacific Ocean

The proposed flight test operations would have no discernible or measurable effect on the ocean’s overall physical and chemical properties, and thus would have no impacts to the overall marine biology of the Ocean Area ROI for both PMRF and RTS. Moreover, the proposed test flight operations would have no discernible effect on the biological diversity of either the pelagic or benthic marine environments. The proposed activities would take place in the open ocean, or pelagic zone, which is far removed from land and contains approximately 2 percent of marine species. The potential for impacts exists from the GBI and target missile booster's fall to the ocean surface and from the target payload fall to the ocean surface. Of particular concern is the potential for impacts to marine mammals from both auditory and non-auditory effects. Potential auditory effects include behavioral disturbance (including displacement), acoustic masking (elevated noise levels that drown out other noise sources), and (with very strong sounds) temporary or permanent hearing impairment. Potential non-acoustic effects include physical impact by falling debris, entanglement in debris, and contact with or ingestion of debris or hazardous materials. Potential adverse effects could occur from sonic boom overpressures, shock wave impact or direct contact, ingestion of toxic solutions generated from the unburned propellant mixed with seawater, and ingestion of pieces of unburned propellant. The potential effects to marine biological resources from installation and operation of the SBX would be similar to those described in section 4.3.3.3 and 4.6.3.2.

Hazardous Materials Deposition

The National Aeronautics and Space Administration conducted a thorough evaluation of the effects of missile systems that are deposited in seawater. It concluded that the release of hazardous materials aboard missiles into seawater would not be significant. Materials would be rapidly diluted and, except for the immediate vicinity of the debris, would not be found at concentrations identified as producing any adverse effects. The Pacific Ocean depth in the vicinity of the launch area is thousands of meters (feet) deep, and consequently impact from the fuel is expected to be minimal. The rocket components would immediately sink to the ocean bottom, out of reach from marine mammals, sea turtles, and most other marine life (U.S. Department of the Air Force, 2002). Unburned solid fuel is hard and rubber-like, and any ammonium perchlorate would dissolve slowly out of the rubber-like binder, producing ammonia and chlorine that would disperse into the marine waters. Were hazardous materials to leach out of the intercept debris, the great volume of water in the ocean would dilute the contaminant to acceptable levels. The solid fuel’s aluminum oxide is insoluble; in addition, as the fuel slowly
dissolves, its outer layers become spongy, further retarding dissolution. Thus, no toxic levels of ammonia, chlorine, or aluminum would be expected. A recent study conducted for the U.S. Air Force (Lang, et al, 2000) measured the amount of perchlorate lost from solid propellant samples immersed in fresh and salt water. From the measurement of the concentration of the perchlorate ion in solution, the mass fraction loss of the propellant sample due to perchlorate leaching was calculated. The results are presented in section 4.1.14, KLC Water Resources, table 4.1.14-2. As shown in the table, it would take approximately 270 days for 90 percent of the perchlorate to leach out of solid propellant that lands in the ocean (at 29°C [84°F]). The perchlorate would be expected to be diluted as it mixes with the surrounding water.

Any area affected by the slow dissolution of the propellant would be relatively small due to the size of the rocket motor or propellant pieces relative to the quantity of seawater. (Federal Aviation Administration, 1996)

Under nominal launch conditions when the relative humidity is less than 100 percent, deposition of hydrogen chloride gas on the surface of the sea would not be significant. Analyses for the most conservative case, where rain would be present soon after test firing the advanced solid rocket motor, concluded that acid deposition to surface water would not result in any impacts to larger surface water bodies in the area. This analysis was based on the buffering capacity of fresh water, which is considerably lower than the buffering capacity of sea water; therefore, it is expected that even for the most conservative case condition where all of the hydrogen chloride emission falls over the open ocean area, the pH level would not be depressed by more than 0.2 standard units for more than a few minutes. (U.S. Department of the Navy, 1998)

Mathematical modeling results of advanced solid rocket motor tests indicated the maximum deposition of aluminum oxide would measure about 1.6 milligrams per square meter. Aluminum oxide is not considered toxic under natural conditions but may contribute potentially harmful species of soluble aluminum forms under acidic conditions. It is difficult to quantify the portion of aluminum oxide that reacts with hydrogen chloride to form additional toxic aluminum species. The most conservative approach assumes that all of the aluminum oxide deposited has reacted with hydrogen chloride. With this extremely conservative assumption, the deposition of about 1.6 milligrams per square meter of aluminum oxide equals approximately 0.0054 milligram per liter of aluminum at a water depth of 0.15 meter (0.5 foot). This analysis is based on the assumption that it would not be raining at the time of the test event or within 2 hours after the event. (U.S. Department of the Navy, 1998)

No solid propellant would remain in the spent Long-Range Air Launched Target rocket motors that impact in the ocean. The residual aluminum oxide and burnt hydrocarbon coating the inside of the motor casings would not present any toxicity concerns. However, residual amounts of hydraulic fluid contained in the first-stage motor and the contents of various batteries onboard the rocket motors and the reentry vehicle may mix with the seawater, causing contamination. The release of such contaminants could potentially harm marine life that comes in contact or ingests the toxic solutions. (U.S. Department of the Air Force, 2002)

It is also expected that, even in the most conservative scenario of an on-ship or early flight failure where all of the propellant is ignited and all of the hydrogen chloride and aluminum oxide is deposited, any toxic concentration of these products would be buffered and diluted by sea water to nontoxic levels within minutes. Consequently, any impacts from accidental release would be very transient. (U.S. Department of the Navy, 1998)
Debris

Debris impact and booster drops in the BOA could occur within the 322-kilometer (200-mile) limit of the Exclusive Economic Zone of affected islands. The natural buffering capacity of seawater and the strong ocean currents would neutralize reaction to any release of the small amount of liquid propellant contained within the Divert and Attitude Control System or Liquid Propellant Missile. Analysis in the Marine Mammal Technical Report, prepared in support of the Point Mugu Sea Range EIS, determined that there is a very low probability that a marine mammal would be killed by falling missile boosters, targets, or debris as a result of tests at the Point Mugu Sea Range (less than 0.0149 marine mammals exposed per year). The potential for an object or objects dropping from the air to affect marine mammals or other marine biological resources is less than $10^{-6}$ (1 in 1 million). The probability of a spent missile landing on a cetacean or other marine mammal is remote.

This probability calculation was based on the size of the area studied and the density of the marine mammal population in that area. The analysis concluded that the effect of this missile debris and intact missiles coming down in the open ocean would be negligible. The range area at Point Mugu is smaller (93,200 square kilometers [27,183 square nautical miles]) than the PMRF range area (144,000 square kilometers [42,000 square nautical miles]), and the density of marine mammals at Point Mugu is larger than the density found at PMRF. It is reasonable to conclude that the probability of a marine mammal being injured or killed by missile or debris impact from U.S. Navy testing at PMRF is even more remote than at Point Mugu, since the area at PMRF is larger and the density of marine mammals is smaller. Following formal consultation, the National Marine Fisheries Service concluded that the Proposed Action is not likely to adversely affect any marine mammal species. (U.S. Department of the Navy, 1998)

The splashdown of the first- and second-stage target missile boosters and defensive missile boosters, and the target vehicle’s and defensive missile’s payloads in the case of an unsuccessful intercept, is planned to occur in open ocean waters thousands of meters (feet) deep at considerable distance from the nearest land. The parts of solid rocket motor propellant expelled from a destroyed or exploded rocket motor that fall into the open ocean would most likely sink to the ocean floor at depths of thousands of meters (feet). At such depths, the propellant parts would be out of the way of feeding marine mammals. (U.S. Department of the Navy, 1998)

Following the Long-Range Air Launched Target missile launch, the Booster Extraction System would continue a slow descent by parachute until impacting the water. Although the impact would occur at a reasonably slow velocity, the falling 1,225-kilogram (2,700-pound) pallet could strike and injure or kill a marine mammal or sea turtle. As previously discussed, however, the probability of striking an animal within the ROI is extremely remote. (U.S. Department of the Air Force, 2002)

The eight parachutes used to extract and prepare the Long-Range Air Launched Target missile for launch would sink to the ocean bottom, along with the aluminum pallet. These parachutes, 4.6 to 28.7 meters (15 to 94 feet) in diameter, could cause entanglement of a marine mammal or sea turtle and potential drowning. However, such entanglement would be very unlikely since a parachute would either have to land directly on an animal, or an animal would have to swim blindly into it before it sinks to the ocean floor. The potential for a marine mammal or sea turtle to be in the same area and have physical contact with a parachute is remote. (U.S. Department of the Air Force, 2002)
**Ingestion of Pieces of Unburned Propellant**

Because of the slow rate at which the toxic materials dissolve out of the solid fuel matrix, the concentration and toxicity of dissolved solid rocket motor fuel in the ocean from the unexpended rocket motor, or portions of it, is expected to be negligible and without any substantial effect.

The parts of solid rocket motor propellant expelled from a destroyed or exploded rocket motor that fall into the ocean would most likely sink to the ocean floor at depths of thousands of meters (feet). At such depths the propellant parts would be out of the way of feeding marine mammals.

**Noise**

Potential auditory effects include behavioral disturbance (including displacement), acoustic masking (elevated noise levels that drown out other noise sources), and (with very strong sounds) temporary or permanent hearing impairment. Injury by the shock wave resulting from impact of a large, fast-moving object (such as a missile booster or target vehicle) with the water surface could be considered either an acoustic or non-acoustic effect. TTS, which is the temporary shift in hearing thresholds during and after exposure to high noise levels, is used as a measure of temporary reduction in hearing sensitivity.

For sound levels at or somewhat above the TTS threshold, hearing sensitivity recovers rapidly after exposure to the noise ends. Much greater single noise exposures would be required to result in permanent hearing damage, while lesser noise levels could involve only minor behavioral responses with no effect on hearing sensitivity.

**Sonic Boom Overpressure Impacts**

The missiles could generate a sonic boom upon reentry. Each missile would propagate a unique sonic boom contour depending upon its mass, shape, velocity, and reentry angle, among other variables. The location of the possible impact point would vary depending upon the particular flight test profile. It is therefore difficult to produce the specific location, extent, duration, or intensity of sonic boom impacts upon marine life. These noise levels would be of very short duration.

According to analysis provided in the Navy’s Point Mugu Sea Range EIS, brief transient sounds such as sonic booms are unlikely to result in significant adverse effects to pinnipeds in the water. Pinnipeds seem tolerant of noise pulses from sonic booms, although reactions may occur. Temporary displacement, less than 1 or 2 days, is considered a less than significant impact. Momentary startle or alert reactions in response to a single transient sound such as a sonic boom are not considered a significant adverse effect to whales. Baleen whales (humpback, gray, and bowhead) have often been observed behaving normally in the presence of strong noise pulses from sources such as distant explosions and seismic vessels. Most gray and bowhead whales show some avoidance of areas where these noise pulses with pressures exceeding 170 dB or 1micropascal are repeated. (Department of the Navy, Naval Air Warfare Center Weapons Division, 2002)

The noise level thresholds of impact to marine life in general, and marine mammals in particular, are currently the subject of scientific analysis. However, due to the small open ocean area that could potentially be impacted and the relatively low number of species present it is highly unlikely that sonic booms for the missiles analyzed in this EIS would significantly affect marine
species. In addition, since different species of marine mammals have varying sensitivity to different sound frequencies and may be found at different locations and depths in the ocean, it is difficult to generalize sound impacts to marine mammals from missile impacts in the BOA. Should consensus emerge from the scientific analysis about the effects of underwater noise on marine mammals, it would then be possible to predict the consequences of a particular sonic boom contour upon marine mammals in the vicinity.

Recent analysis by Cheng and Lee has shown that disturbances from acoustic sources produced by interaction of a surface wave train with an incident sonic boom wave would attenuate in deep water at a rate much lower (slower) than those predicted by Sawyer’s theory for a flat (non-wavy) ocean, and would accordingly overwhelm the latter at large depth. Experimental and theoretical research on underwater impact from sonic booms are performed to ascertain the significant influence of wavy ocean surface on sonic boom penetration power and to determine, through application of validated model to aircraft and space-launch examples, if predicted signal intensity and characteristics at depth belong to ranges and types that may allow meaningful impact assessment in the study of marine mammals. (Space and Missile Systems Center, Environmental Management Branch, 2002)

**Shock Wave Impact**

The first-, second-, and third-stage target missile boosters and the target vehicle’s payload, which all fall to the ocean surface, would impart a considerable amount of kinetic energy to the ocean water upon impact. Missiles and targets would hit the water with speeds of 91 to 914 meters (300 to 3,000 feet) per second. It is assumed that the shock wave from their impact with the water would be similar to that produced by explosives. At close ranges, injuries to internal organs and tissues would likely result. However, injury to any marine mammal by direct impact or shock wave impact would be extremely remote (less than 0.0006 marine mammals exposed per year). The splashdown of the target missile boosters and payload is planned to occur in open ocean waters thousands of meters (feet) deep at considerable distance from the nearest land. (U.S. Army Space and Missile Defense Command, 2001b)

Standard range warning and checking procedures would check for visible large concentrations of marine mammals in the area of the target launch, trajectory, and first-stage impact area. Patrol and surveillance aircraft would be dispatched before launch to search the water surface. If contacts are made and confirmed, the Flight Safety Officer would determine whether to continue on schedule, delay the test flight, or postpone it until another day.

**4.11.2.4 Cumulative Impacts**

No substantial impacts to the Gulf of Mexico or to the open ocean area and its wildlife have been identified from current and past missile test activities. Prior analysis has not identified a significant potential for cumulative impacts. It is not likely that the proposed activities, in conjunction with current or anticipated launches, would exceed the current level of activity in these areas. GMD ETR-related tests would be discrete, short-term events, and no adverse cumulative impacts are anticipated.
4.11.2.5 Mitigation Measures

No biological resources mitigation measures are proposed for GMD ETR activities conducted in the Gulf of Mexico or the open ocean area. These activities would adhere to the terms and conditions imposed by the National Marine Fisheries Service on missile launches.

4.11.3 HEALTH AND SAFETY—BROAD OCEAN AREA

4.11.3.1 Gulf of Mexico

No Action Alternative

Under the No Action Alternative, the GMD ETR would not be developed, and the proposed test activities in the Gulf of Mexico would not occur.

Proposed Action

The Gulf of Mexico ROI is defined as the overwater area that would be potentially affected by the initial sea trials of the SBX platform and full power testing of the SBX. The sea trials are designed to ensure maneuverability and control of the vessel. The total amount of radar RF radiation would be approximately 5 to 6 hours per week during testing. The location of the testing has not been determined; however, it would be conducted in areas that would minimize impacts to aircraft and marine vessels. SBX operations would be coordinated with the FAA, Coast Guard and other groups or agencies as appropriate, and NOTMARs and NOTAMs would be issued to warn aircraft and surface vessels of the testing. Therefore, no health and safety impacts to airspace/aircraft or mariners are anticipated.

As described in section 4.11.1.1, an EMR/EMI survey and analysis and DD Form 1494 would be required as part of the spectrum certification and frequency allocation process. A completed DD Form 1494 that has been processed and approved by the appropriate national and international authorities would be required before SBX testing. No impact to health and safety is expected.

4.11.3.2 Enroute from Gulf of Mexico to Pacific Ocean

No Action Alternative

Under the No Action Alternative, the GMD ETR would not be developed, and the proposed test activities en route from the Gulf of Mexico to the Pacific Ocean would not occur.

Proposed Action

The SBX would use existing shipping routes along the coast of South America to get from the Gulf of Mexico to the Pacific Ocean. Full power testing of the SBX would occur during this transit period. The total amount of radar RF radiation would be approximately 5 to 6 hours per week during testing. The location of the testing has not been determined; however, it would be conducted in areas that would minimize impacts to aircraft and marine vessels. SBX operations would be coordinated with the FAA, Coast Guard, and other groups or agencies as appropriate and NOTMARs and NOTAMs would be issued to warn aircraft and marine surface vessels of the testing. Therefore, no health and safety impacts to airspace/aircraft or mariners are anticipated.

As described in section 4.11.1.1, an EMR/EMI survey and analysis and DD Form 1494 would be required as part of the spectrum certification and frequency allocation process. A completed DD
Form 1494 that has been processed and approved by the appropriate national and international authorities would be required before SBX testing.

4.11.3.3 Pacific Ocean

No Action Alternative

Under the No Action Alternative, the GMD ETR would not be developed, and the proposed full range of GMD flight test activities in the Pacific BOA would not take place. Ongoing missile flight test activities would continue to use the existing special use airspace and other areas in the Pacific BOA. The continuing activities would not conflict with any commercial shipping lanes or airspace use plans, policies, and controls.

Proposed Action

The Proposed Action in the Pacific BOA would include missile booster drop zones, missile intercepts, and intercept debris. In addition, the launching of mobile sea launch targets and air launch targets could have airspace use or commercial shipping lane impacts that would be essentially the same as the ground launched missiles. The Proposed Action would also include transit of the SBX from a PSB to the appropriate SBX performance region, SBX operations within the performance region in support of GMD flight tests, and transit back to a PSB.

For sea-launch target launches, the airspace is not heavily used by commercial aircraft and is far removed from the en route airways and jet routes crossing the North Pacific, so the impacts to controlled and uncontrolled airspace would be minimal. GMD ETR activities have the potential for intercept and target debris impacts to waters normally occupied by commercial shipping. The majority of international trade crossing the Pacific between Asia and North America uses routes of least distance, usually via the great circle route. Depending upon the individual scenarios, the actual debris impact area would be small.

SBX operations would be coordinated with the FAA, Coast Guard, and other groups or agencies as appropriate, and NOTMARs and NOTAMs would be issued to warn aircraft and marine surface vessels of the radar testing/operation. SBX tests would be conducted in areas that would minimize impacts to marine transportation. The SBX would generally be able to operate from a location that does not interfere with the air routes crossing the region. If the SBX were to operate in an air route location, non-participating aircraft could be routed around the SBX operating area. Continued monitoring of testing areas for other marine vessels would take place to ensure such areas remain clear.

As described in the section 4.11.1.1, an EMR/EMI survey and analysis and DD Form 1494 would be required as part of the spectrum certification and frequency allocation process. A completed DD Form 1494 that has been processed and approved by the appropriate national and international authorities would be required before SBX operations in the Pacific Ocean. The spectrum certification process would identify coordination requirements that would be followed by the SBX for all operations.

4.11.3.4 Cumulative Impacts

The Proposed Action would result in up to five launches (target and GBI combined) per year. This would be consistent with current levels of missile activities in the open ocean area. Each launch would result in falling inert debris such as target boosters, target re-entry vehicles,
interceptor missiles, target and intercept missile debris, or pallets and associated debris (metal fragments) and parachutes being deposited into the open ocean. However, each flight test and SBX test is a discrete short-term event, no population centers would be in the affected areas, and the Proposed Action would require the administration of NOTAMs and NOTMARs to warn aircraft and surface vessels of the potentially hazardous areas and allow them ample time to avoid hazards. Other missile test programs that could potentially affect the same area as the GMD ETR would also be short-term events and would not occur at the same time as the GMD ETR tests. Therefore, the potential for additive, incremental cumulative impacts from debris hazards or EMR exposure is extremely limited.

4.11.3.5 Mitigation Measures
Coordination between range personnel and with the FAA, Coast Guard, and other groups or agencies, as well as issuance of NOTMARs and NOTAMs, would be routine part of the Proposed Action. Additional health and safety mitigation measures are not proposed for GMD ETR activities.

4.11.4 TRANSPORTATION—BROAD OCEAN AREA

4.11.4.1 Gulf of Mexico
The initial sea trials would take place in the Gulf of Mexico and are designed to ensure maneuverability and control of the vessel. Since these tests may be run in parallel with the payload installation and checkout tests, mass simulators may be used to represent uninstalled portions during the stability and control evaluations. The emphasis would be on identifying and correcting problem operating conditions, such as vibrations that result from the installation of diesel and electric generators above the main deck or the vessel’s electric thrusters. These activities would not affect commercial shipping routes.

4.11.4.2 Enroute from Gulf of Mexico to Pacific Ocean
The SBX would use existing shipping routes along the coast of South America to get from the Gulf of Mexico to the Pacific Ocean. During this transit period, periodic testing of the SBX at predetermined locations would occur. Appropriate NOTMARs and NOTAMs would be issued to warn aircraft and surface vessels of the testing.

4.11.4.3 Pacific Ocean
GMD ETR activities have the potential for intercept and target debris impacts to waters normally occupied by commercial shipping. The majority of international trade crossing the Pacific between Asia and North America uses routes of least distance, usually via the great circle route. Depending upon the individual scenarios, the actual debris impact area would be small.

Prior warning of GMD ETR activities would enable commercial shipping to follow alternative routes away from the test area. The process is simplified by the lack of any formal shipping lanes in the northern Pacific. Safety procedures would be employed to determine that the impact areas are clear of surface vessels to ensure that no impact to ocean transportation would occur.

During the transit period into and through the Pacific Ocean area, periodic testing by the SBX (satellite and calibration device tracking) at predetermined locations would occur. Appropriate
NOTMARs and NOTAMs would be issued to warn aircraft and surface vessels of the testing, and those tests would be conducted in areas that would minimize impacts to marine transportation. The SBX would generally be able to operate from a location within the SBX performance region that does not interfere with the air routes crossing the region. If the SBX were to operate in an air route location, non-participating aircraft could be routed around the SBX operating area. Continued monitoring of testing areas for other marine vessels would take place to ensure such areas remain cleared. As mentioned previously, a completed DD Form 1494 would be required prior to SBX operations in the Pacific Ocean, and would assist in defining the operating area for the SBX.

4.11.4.4 Cumulative Impacts
Cumulative impacts would be minimized through early notification of aircraft and surface vessels through NOTMARs and NOTAMs, allowing commercial shipping to find alternative routes if necessary.

4.11.4.5 Mitigation Measures
Coordination between range personnel and with the FAA, Coast Guard, and other groups or agencies, as well as the aforementioned issuance of NOTMARs and NOTAMs, would be a routine part of the Proposed Action. No additional transportation mitigation measures are proposed.

4.12 CONFLICTS WITH FEDERAL, STATE, AND LOCAL LAND USE PLANS, POLICIES, AND CONTROLS FOR THE AREA CONCERNED

The proposed program activities at KLC, Midway, RTS, PMRF, Vandenberg AFB, Pearl Harbor, NBVC Port Hueneme/San Nicolas Island, Naval Station Everett, Port Adak, and the Port of Valdez would be consistent with the existing land use. The proposed activities would not alter the use of the sites that currently support missile and rocket testing. Development of the SBX PSB would be in accordance with federal, state, and local planning plans and policies. All activities at RTS would comply with federal laws and regulations, the UES, and the Compact of Free Association between the RMI and the United States, and with regional and local land uses, policies, and regulation agreements. PMRF maintains federal jurisdiction for on-base land use; therefore, state and local land use laws are preempted.

Any potential conflicts with land use plans, policies, and controls would be a primary focus of agreements that would be negotiated with all affected federal, state, regional, and local agencies as applicable before implementation of the Proposed Action. Any closure of state recreational areas would be short-term, episodic events.

4.13 ENERGY REQUIREMENTS AND CONSERVATION POTENTIAL
Anticipated energy requirements of the GMD ETR program would be well within the energy supply capacity of all facilities. Energy requirements would be subject to any established energy conservation practices at each facility. No additional power generation capacity other than the potential use of generators would be required for any of the GMD ETR activities.
4.14 NATURAL OR DEPLETABLE RESOURCE REQUIREMENTS AND CONSERVATION POTENTIAL

Other than various structural materials and fuels, the program would require no significant natural or depletable resources.

4.15 ADVERSE ENVIRONMENTAL EFFECTS THAT CANNOT BE AVOIDED

In general, most known adverse effects resulting from implementation of the GMD ETR program would be mitigated through project planning and design measures, consultation with appropriate agencies, and the use of Best Management Practices. As a result, most potential adverse effects would be avoided, and those that could not be avoided should not result in a significant impact to the environment.

Adverse environmental effects that cannot be avoided include removal of vegetation at the proposed construction sites; minor short-term noise impacts to and startling of wildlife; the release of small amounts of pollutants into the atmosphere, the ground, and ocean; and minor increased generation of hazardous materials at program-related sites. Consultation with the appropriate agency would assist in developing mitigation measures to minimize the potential impacts to wetlands. Some short-term program-related impacts to air quality, soils, and water resources may occur. Any hazardous waste generated would be managed in compliance with DoD, and other applicable federal, state, and local regulations.

EMR levels would not exceed safety guidance and would not affect the public. During the construction phase there would be temporary disturbance to the immediate area around new fiber optic cable line routes; however, once the cable is installed, there would be no long-term impacts.

4.16 RELATIONSHIP BETWEEN SHORT-TERM USE OF THE HUMAN ENVIRONMENT AND THE MAINTENANCE AND ENHANCEMENT OF LONG-TERM PRODUCTIVITY

Proposed GMD ETR activities would take advantage of existing facilities and infrastructure to the extent practicable. The use of land on Midway for an IDT and COMSATCOM would not eliminate options for continued and future use of the island. The uses of the sites at locations that were, or are, to support missile and rocket launches would not be altered. Therefore, the Proposed Action does not eliminate any options for future use of the environment for the locations under consideration.

4.17 IRREVERSIBLE OR IRRETRIEVABLE COMMITMENT OF RESOURCES

The Proposed Action is not expected to result in the loss of threatened or endangered species and no loss of cultural resources, such as archaeological or historic sites. There would be the use of irretrievable resources (e.g., construction materials, fuel, and labor). There would be some minor loss of biological habitat and wetlands, but impacts would be minimized through the
implementation of mitigation measures. Sensitive biological habitat would be avoided to the maximum extent practicable. Proposed activities would not irreversibly curtail the range of potential uses of the environment. Moreover, there would be no preclusion of development of underground mineral resources that were not already constrained.

Although the proposed activities would result in some irreversible or irretrievable commitment of resources such as various construction materials, minerals, and labor, this commitment of resources is not significantly different from that necessary for many other defense research and development programs carried out over the past several years. Proposed activities would not commit natural resources in significant quantities.

4.18 FEDERAL ACTIONS TO ADDRESS PROTECTION OF CHILDREN FROM ENVIRONMENTAL HEALTH RISKS AND SAFETY RISKS (EXECUTIVE ORDER 13045, AS AMENDED BY EXECUTIVE ORDER 13229)

This EIS has not identified any environmental health and safety risks that may disproportionately affect children, in compliance with Executive Order 13045, as amended by Executive Order 13229.

4.0 ENVIRONMENTAL CONSEQUENCES

This chapter describes the potential environmental consequences associated with each location that may be affected by the Proposed Action, action alternatives, and the No Action Alternative along with the identification of potential cumulative impacts and mitigation measures. To assess the potential for and significance of environmental impacts from the proposed program activities, a list of activities was developed (chapters 1.0 and 2.0) and the environmental setting was described, with emphasis placed on any special environmental sensitivities (chapter 3.0). Program activities were then compared with the potentially affected environmental components to determine the environmental impacts of the proposed activities. To help define the affected environment and determine the significance of program-related effects, personal, written, and telephone contacts were made with applicable agencies.

Cumulative impacts result from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of who undertakes such actions. Cumulative impacts can result from individually minor, but collectively significant, actions taking place over a period of time. For this EIS, potential cumulative impacts are addressed for past, present, and future actions. Future actions were identified based on review of installation and regional land use plans and discussions with installation and regional planners.

Consistent with CEQ regulations, the scope of the analysis presented in this section was defined by the range of potential environmental impacts that could result. Resources that have a potential for impacts were considered in the analysis to provide the decision makers with sufficient evidence and analysis for evaluation of potential effects of the action. For this EIS, the environment is discussed in terms of 14 resource areas, which are discussed as applicable for each location.

Sections 4.1 through 4.11 provide discussions of the potential environmental consequences of the proposed GMD ETR program activities and the No Action Alternative. The amount of detail presented in each section is proportional to the potential for impacts. Sections 4.12 through 4.18 provide discussions of the following with regard to proposed program activities: conflicts with federal, state, and local land use plans, policies, and controls for the area concerned; energy requirements and conservation potential; natural or depletable resource requirements and conservation potential; adverse environmental effects that cannot be avoided; relationship between short-term use of the human environment and the maintenance and enhancement of long-term productivity; irreversible or irrevocable commitment of resources; Executive Order 13045, Federal Actions to Address Protection of Children from Environmental Health Risks and Safety Risks; and a summary of unresolved issues.
4.1 KODIAK LAUNCH COMPLEX

4.1.1 AIR QUALITY—KODIAK LAUNCH COMPLEX

This section addresses potential environmental impacts from changes in the air quality environment due to the proposed construction and operation of the GBI, target, IDT, and sensor elements of the GMD ETR at KLC, as well as the identification of potential cumulative impacts and mitigation measures. Impacts considered include potential effects from ongoing or planned activities at this site. Potential impacts were determined using the following criteria:

- Operations within attainment areas that could cause a detrimental change in attainment status of the area
- Increases in ambient air pollutant concentration that could cause exceedances of the NAAQS or state AAQS
- The U.S. Air Force standard for hydrogen chloride is 2 parts per million (ppm) for 60 minutes and 10 ppm for a maximum instantaneous level. These standards are based upon measured and estimated launch emission exposure concentrations and durations in the event of normal and catastrophic launches (National Research Council, Commission of Life Sciences, Board of Environmental Studies and Toxicology, Committee on Toxicology, Subcommittee on Rocket Emission Toxicants, 1998).
- The standard used for aluminum oxide is 150 micrograms per cubic meter (μg/m³) is based upon the maximum NAAQS level of PM-10 concentrations over a 24-hour period.
- Increases in air pollutant concentrations greater than 1 μg/m³ (averaged over 24 hours) from new or modified major stationary sources within 10 kilometers (6 miles) of a Class I area.

Appendix B includes a detailed description of these air quality standards.

4.1.1.1 No Action Alternative

Missile Defense Agency

Under the MDA’s No Action Alternative, launches of all types covered by the launch site operator’s license would continue to occur at KLC, although the GMD ETR would not be established and GBI and target launch scenarios would not be tested under more operationally realistic conditions. Missile propellant information for previous and predicted launches at KLC is shown in table 4.1.1-1.

The KLC EA predicted, under worst-case meteorological conditions, that NAAQS, Alaska AAQS, and U.S. Air Force and Non-criteria Pollutant guidance levels would not be exceeded during up to nine launches per year of the Athena-2, using Castor 120™ motors for propulsion (Federal Aviation Administration, 1996).

Operational emissions predicted at KLC include existing stationary sources. These stationary sources include three standby diesel generators operating at a maximum of 5 hours during launches, 1 hour per week for testing during non-launch periods and during commercial power outages (approximately 240 hours per year). Air quality impacts from these sources are considered to be temporary. (Federal Aviation Administration, 1996) Table 4.1.1-2 lists the estimated emissions generated by the four standby generators at KLC. KLC currently maintains a Pre-approved Limit Permit for these generators.

Upper Atmosphere
According to the KLC EA, potential contributions to the upper atmosphere include emissions from ground-level operations and exhaust emissions from launch vehicles. Up to nine launches per year of the Athena-2, using the Castor 120™ motors for propulsion, were determined by the KLC EA to have a small impact on the levels of ozone found in the stratosphere; however, the release of chlorine (from the chemical reaction from the release of hydrogen chloride) and alumina (from the chemical reaction from the release of aluminum oxide) into the stratosphere would make a minimal contribution to the overall impact of ozone depletion. (Federal Aviation Administration, 1996)
Federal Aviation Administration
Under the FAA’s No Action Alternative, the launch site operator license for KLC would not be renewed and no launches would be allowed to occur from KLC after September 2003. Therefore, no impacts to air quality would occur from launches at KLC.

4.1.1.2 Alternative 1

4.1.1.2.1 Ground-Based Interceptors

Construction
Construction at KLC, as described in section 2.3.1.1, would disturb approximately 14.4 hectares (35.5 acres). The majority of the ground disturbance would occur within 1 year, and it is projected that construction would take up to 15 months to complete. Construction emissions vary from day to day and activity to activity, with each activity having its own potential to release emissions. Because of the variability in timing and intensity of construction, estimating construction-phase pollutant emissions is difficult. Nevertheless, it is assumed that there would be PM-10 impacts from ground disturbance and other pollutants (carbon monoxide, oxides of nitrogen, volatile organic compounds, and oxides of sulfur) primarily emitted from construction equipment exhaust. Potential construction emissions were determined by using emission factors from various sources including the EPA. Conservative estimates are based on building square footage, acreage disturbed, and duration of construction, as well as general meteorological and soil information. For purposes of determining the level of fugitive dust generated, it was assumed all grading would be accomplished during the first year. Potential fugitive dust amounts were estimated using Air Quality Thresholds of Significance spreadsheets. Table 4.1.1-3 lists estimated carbon monoxide, oxides of nitrogen, volatile organic compounds, oxides of sulfur, and PM-10 emissions from construction equipment, earth moving and commuting workers anticipated during 15 months of construction of GBI facilities. Best Management Practices including proper tuning and preventative maintenance of construction vehicles would serve to minimize exhaust emissions and maximize vehicle performance.

<td>0.14 (0.15)</td>
</tr>
<tr>
<td>PM-10</td>
<td>34 (37.5)</td>
<td>-</td>
</tr>
</tbody>
</table>

Approximately 68 metric tons (75 tons) of PM-10 could be produced during the construction of the facilities. Best Management Practices would be used to reduced PM-10 emissions by half to approximately 34 metric tons (37.5 tons) using dust suppression measures such as periodically watering the areas being graded, minimizing unnecessary traffic, reducing vehicle speeds near
the work areas, and wet sweeping or otherwise removing soil and mud deposits from paved roadways and parking areas.

For conservative analytical purposes, it is assumed that 50 of the 100 additional construction personnel would utilize an existing mancamp located approximately 4 kilometers (3 miles) from the construction site. The remaining 50 were assumed to commute to and from the City of Kodiak or to and from accommodations in the area surrounding KLC. Commuting emission levels were based upon federal primary exhaust emission standards for vehicles for an entire day of commuting (to KLC and back). If either the additional mancamp was constructed or the existing mancamp was added to, then all 100 construction personnel would be housed in close proximity to KLC, greatly reducing the potential commuting emissions.

Construction emission levels are below de minimis levels set by the federal government for non-attainment areas. The de minimis thresholds are federal limits listed in 40 CFR 51.583(b)(1). Federal actions with emissions below the de minimis levels are presumed to conform, that is, not cause or contribute to new violations of NAAQS, in areas that are in non-attainment. For the least severe nonattainment areas, the de minimis level for each criteria pollutant (and their precursors, in the case of ozone) is 90.7 metric tons (100 tons) per year.

Construction would be conducted in accordance with applicable federal and state regulations and permits. While the construction would cause an increase in air pollutants, the impact would be both temporary and localized. Once construction ceased, air quality would return to its former level. Since the area is currently in attainment for all federal standards and construction emissions would be within de minimis levels for non-attainment areas, it is anticipated that the proposed construction would not cause exceedances of the NAAQS or Alaska AAQS and would not have a long-term impact to air quality in the area.

Operation

Pre-Launch Activities
The manufacturing of GBI vehicle components would occur offsite in existing facilities that normally perform this type of production, and emissions at these locations have not been included in the scope of this EIS. The components would arrive complete, requiring only final onsite safety and quality checks before assembly.

Pre-launch activities would include the transportation of the interceptor missile boosters, payloads, and support equipment by either air or ship. This transportation would result in some mobile exhaust emission, but these emissions would be intermittent and would not have a measurable impact on regional air quality. The interceptor could arrive at KLC with the EKV attached, or the booster may be shipped separately from the EKV. Either way, integration and assembly operations would be performed at KLC.

Onsite fueling of the interceptor or EKV would not be required; the interceptor motor would utilize pre-loaded solid propellants. Each EKV would contain pre-loaded liquid propellant and oxidizer. The propellants would be delivered to the launch site in pre-filled and sealed tanks that would be ready to be installed onto the vehicle. Installation would only require mechanical tubing connections.
During nominal propellant tank installation, the propellants remain sealed inside their tanks. The likelihood of an accidental release of the liquid fuel or oxidizer would be low. However, if such an accident were to occur, it would most likely occur during missile assembly. Table 4.1.1-4 indicates the results of analysis using the U.S. Air Force Toxic Corridor Model computer model to determine distances at which the Immediately Dangerous to Life and Health (IDLH) health standard could be exceeded assuming all 7.5 liters (2 gallons) of fuel and 5.5 liters (1.5 gallons) of oxidizer were released to the atmosphere during an accident. The IDLH is the level of exposure (not time-weighted) above which it is thought a person would suffer life-threatening or irreversible health effects or other injuries that would impair them from escaping the hazardous environment. The IDLH level was the only level of concern as others are based on time weighted averages over prolonged exposures.

aThe National Institute for Occupational Safety and Health (NIOSH) Immediately Dangerous to Life and Health (IDLH) is the level of exposure (not time-weighted) above which it is anticipated a person would suffer life-threatening or irreversible health effects or other injuries that would impair them from escaping the hazardous environment.
bExceedance Distance—Average of U.S. Air Force Toxic Corridor model results for 15-minute and 30-minute averaging time and multiple stability classes

ppm = parts per million by volume.
mg/m³ = milligrams per cubic meter

Actual hazard distances would depend on the propellant released, the amount released, meteorological conditions, and emergency response measures taken. AADC’s approved SOPs would be implemented and would include personal protection equipment procedures. Establishment of and adherence to these SOPs would minimize the potential hazards to personnel in the unlikely event of an unplanned propellant release. The low likelihood of such an event and the implementation of approved emergency response plans would limit the impact of such a release.

Personnel would include a combination of contractor, military, and government civilian. The largest manpower buildup at KLC would be 55 the first month, 120 the second month, and 235 the third month to support a dual interceptor launch. It is assumed that approximately 50 personnel would be housed at the existing mancamp on Kodiak Ranch. If the additional mancamp is not constructed on KLC or the existing mancamp is not added on to, then it is conservatively estimated that the remaining 185 personnel would commute daily to KLC from accommodations in the surrounding areas and within the City of Kodiak during a peak month. Commuting emission levels were based upon federal primary exhaust emission standards for vehicles for an entire day of commuting (to and from KLC) and estimated to be 2.0 metric tons (2.2 tons) of carbon monoxide and 0.24 metric tons (0.26 tons) of oxides of nitrogen.
Offsite power sources are planned for primary use, with emergency generators supplying backup power. The emergency backup generators would be operated under appropriate permits and restrictions. In addition to the generators themselves, appropriate ASTs would be installed adjacent to each generator. Table 4.1.1-5 lists the generator and AST sizes for each facility. Table 4.1.1-6 lists the possible emissions associated with each generator.

The generators would operate as backup during launches, weekly for testing during non-launch periods, and during commercial outages. The total operating time is estimated at a maximum of 250 hours per year. Use of these generators would require an amendment to the existing Pre-approved Limit Permit.
Table 4.1.1-6 also shows the total emissions from GBI, target, IDT, sensors, and TPS-X at KLC. Although not in a non-attainment area, these totals are below the *de minimis* thresholds and therefore would not cause exceedances of the NAAQS or Alaska AAQS.

**Launch Activities**

Alternative 1 includes up to a total of five missile launches (GBI and target combined) per year at KLC over the duration of the test program. Table 4.1.1-7 lists propellant information for the proposed GBI. Table 4.1.1-8 lists possible emissions from stage one of the proposed single GBI launch.

Source: Nyman, 2003

Dual GBI launches were analyzed using Open Burn/Open Detonation Dispersion Model (OBODM) to determine exhaust emissions of aluminum oxide, hydrogen chloride, and carbon monoxide. Table 4.1.1-9 lists emission concentrations and standards. As shown on table 4.1.1-9, concentrations produced by dual launches of a dual GBI would remain within NAAQS, Alaska AAQS, and U.S. Air Force standards. It is anticipated that a nominal single launch would also remain within NAAQS and U.S. Air Force standards as fewer emissions would be released during a single launch.

While the area KLC is located in is in attainment for all federal emission standards, federal *de minimis* threshold limits listed in 40 CFR were used to compare oxides of nitrogen and carbon monoxide. In the event that five GBIs were launched in a year, the conservatively estimated annual emissions for oxides of nitrogen were determined to be 28.8 metric tons (31.8 tons), below the 45.4-metric-ton (50-ton) standard. Carbon monoxide was calculated at 4.9 metric tons (5.4 tons) for five launches, which is well below the 90.7-metric-ton (100-ton) annual standard.

(1) Based upon NAAQS  
(2) Based upon the maximum NAAQS level of PM-10 concentrations over a 24-hour period  
(3) Based upon Air Force standards that measured and estimated launch emission exposure concentrations and durations in the event of normal and catastrophic launches

Personnel would be evacuated to a safe distance before a launch according to established launch procedures as stated in section 3.1.7, Health and Safety. Due to the mobile nature of the interceptor itself, only a small portion of the launch exhaust would be emitted near the ground. With typical meteorological conditions, prevailing winds from the northwest, the ground-cloud of exhaust would be carried to the ocean. In all cases of weather conditions, significant air quality impacts due to missile launches are not anticipated.

If flight termination becomes necessary, the potential resulting fire would cause short-term impacts to air quality in the form of combustion byproducts and potentially hazardous fumes. Most or all of the solid propellant fuel would likely burn up before being extinguished. These combustion byproducts would be similar to those previously described for a nominal launch.

Modeling using the OBODM was also performed to analyze emissions produced in the highly unlikely occurrence of an on-pad accident involving dual GBIs. The modeling showed that both the 1-hour and peak hydrogen chloride Air Force standards would be exceeded (table 4.1.1-9). The 8-hour, 24-hour, and IDLH hydrogen chloride standards were not exceeded. All other standards would continue to be within NAAQS and Alaska AAQS. The consequences to regional air quality would be localized for both the 1-hour and peak hydrogen chloride Air Force standard (exceedance out to 1 kilometer [0.6 mile] and 3.7 kilometers [2.3 miles], respectively beyond the KLC boundary) and would be of a short duration. The modeling included both day and nighttime meteorological data. The nighttime data is generally very calm wind conditions which results in higher emission concentrations. Due to the highly unlikely potential for a dual accident, the localized short term nature of the air quality exceedence, and the conservative nature of the modeling data inputs, the impact to regional air quality is considered minor.

Post-Launch Activities
Post-launch activities would include the removal of all mobile equipment and assets brought to KLC. A negligible impact would be anticipated to air quality resulting from slightly increased vehicular emissions and localized amounts of fugitive dust (PM-10).
4.1.1.2.2 Targets

Construction

Approximately 10.5 hectares (26 acres) of land would be disturbed during the construction of target facilities. Calculation of construction emissions followed the same methodology as described in section 4.1.1.2.1. Table 4.1.1-10 lists estimated carbon monoxide, oxides of nitrogen, volatile organic compounds, and oxides of sulfur emissions anticipated during up to 15 months of construction of target missile facilities. Best Management Practices, including proper tuning and preventive maintenance of construction vehicles, would serve to minimize exhaust emissions and maximize vehicle performance.

Table 4.1.1-10: Potential Construction Emissions for Target Facilities at KLC

<table>
<thead>
<tr>
<th>Emission</th>

</tr>
<tr>
<td>PM-10</td>
<td>25 (27.5)</td>
<td></td>
</tr>
</tbody>
</table>

Approximately 50 metric tons (55 tons) of PM-10 could be produced during the construction of the facilities. The use of Best Management Practices would reduce this number by half to approximately 25 metric tons (27.5 tons) using dust suppression measures such as periodically watering the areas being graded, minimizing unnecessary traffic, reducing vehicle speeds near the work areas, and wet sweeping or otherwise removing soil and mud deposits from paved roadways and parking areas. Impacts due to personnel at KLC for construction of target facilities would be the same as those described in section 4.1.1.2.1 for construction of GBI facilities.

Operation

Pre-Launch Activities

Pre-launch activities include the transportation of the target to KLC and assembly of the target at KLC. The mobile exhaust emissions resulting from transportation of the target would be intermittent and would not have a measurable impact to regional air quality. The targets would be assembled and stored in the Missile Assembly Building until launch.

If used as a target, the fourth stage of a Peacekeeper target would utilize a single liquid propellant (hydrazine), and onsite fueling would be required. Although total vapor emissions can vary depending on the propellant transfer equipment used and how it is assembled, it is anticipated that only very small amounts (approximately 10 grams [0.4 ounce]) of vapors would be released to the atmosphere during the transfer operation. These normal fueling operations would marginally impact air quality for momentary periods of time.

It is unlikely that a propellant release larger than that described above would occur at KLC. However, if such an accidental release were to occur, it would most likely occur during fueling. A reasonable scenario would involve failure of the transfer equipment or valves. The analysis
assumes a leak contained over a 3-minute period that releases up to 17 liters (4.5 gallons) of hydrazine fuel. Analysis indicated no potential exceedances of the IDLH health standard of 50 ppm. The low likelihood of such an occurrence and the implementation of approved emergency response plans would limit the impact of such a release.

Emergency generators would supply backup power to target facilities with offsite commercial power sources. The emergency backup generators would be operated under appropriate permits and restrictions. In addition to the generators themselves, appropriate ASTs would be installed adjacent to each generator. Table 4.1.1-11 lists the generators and the size of ASTs for each facility.

</tbody>
</table>

The generators would operate as backup during launches, weekly for testing during non-launch periods, and during commercial outages. The total time of operation is estimated at a maximum of 250 hours per year. Emissions produced during the generators’ expected limited operation are listed in table 4.1.1-6. Use of these generators would require an amendment to the existing Pre-approved Limit Permit. These levels of emissions would not be expected to impact regional air quality.

Launch Activities

Proposed target launches would be similar to previous target launches at KLC. These land launched target missiles could consist of one of several types of missiles including Strategic Target System, Minuteman II Target, Peacekeeper Target, and Trident I (C4) Target. Table 4.1.1-12 lists missile propellant information, and table 4.1.1-13 lists potential emission constituents during Stage I for each proposed missile. A total of five missile launches (GBI and/or target) per year would be anticipated at KLC over the duration of the program.

Each launch is a discrete event. The logistics of the launch would allow sufficient time between launches so that no exhaust from one launch would impact the ambient air quality of another launch. The conclusion presented in the KLC EA was that overall impacts to regional air quality are not expected to be adverse and would remain within NAAQS and state AAQS for a single launch of the Athena 2 missile with the Castor 120™ motor. (Federal Aviation Administration, 1996) The nominal launch of a single Peacekeeper Target is anticipated to remain within NAAQS, Alaska AAQS, and Air Force standards as, the first stage of a Peacekeeper Target is a military version of the Castor 120 motor used in the Athena 2 missile.

Dual Peacekeeper Target launches were analyzed using OBODM to determine exhaust emissions of aluminum oxide, hydrogen chloride, and carbon monoxide. Dual emissions were modeled using the Peacekeeper Target as it is the largest of the proposed target vehicles. Emission concentrations and standards are listed in table 4.1.1-14. As shown in table 4.1.1-14, the level of hydrogen chloride would be below the 1-hour Air Force standard, but would exceed the peak hydrogen chloride standard for a short duration (out to a distance of 400 meters (1312 feet) beyond the KLC boundary). The 8-hour, 24-hour, and IDLH hydrogen chloride standards were not exceeded. Other emissions are shown to be within NAAQS standards.

(1) Based upon NAAQS
(2) Based upon the maximum NAAQS level of PM-10 concentrations over a 24-hour period
(3) Based upon Air Force standards that measured and estimated launch emission exposure concentrations and durations in the event of normal and catastrophic launches

KLC is considered to be in attainment for all federal emission standards; however, federal de minimis threshold limits listed in 40 CFR were used to compare levels of carbon monoxide and oxides of nitrogen. In the event that five Peacekeeper Target launches occur in a year, the conservative calculation of annual emissions of carbon monoxide would be 48.8 metric tons (53.8 tons), which is below the 90.7-metric-ton (100-ton) annual standard. Emissions of oxides of nitrogen were estimated to be 18.3 metric tons (20.2 tons), also below the de minimis standard of 45.3 metric tons (50 tons).

Personnel would be evacuated to a safe distance before a launch according to established launch procedures as stated in section 3.1.7, Health and Safety. Due to the mobile nature of the target missiles, only a small portion of the launch exhaust would be emitted near the ground. With typical meteorological conditions, prevailing winds from the northwest, the ground-cloud of exhaust would be carried to the ocean. In all cases of weather conditions, significant air quality impacts due to missile launches are not anticipated.

If flight termination becomes necessary, the potential resulting fire would cause short-term impacts to air quality in the form of combustion byproducts and potentially hazardous fumes. Most or all of the solid propellant fuel would likely burn up before being extinguished. These combustion byproducts would be similar to those previously described for a nominal launch.

Modeling using the OBODM was also performed to analyze emissions produced in the highly unlikely occurrence of on-pad accidents involving dual Peacekeeper Targets. The model results show that both the 1-hour and peak hydrogen chloride Air Force standards would be exceeded (table 4.1.1-14). The 8-hour, 24-hour, and IDLH hydrogen chloride standards were not exceeded. All other standards would continue to be within NAAQS and Alaska AAQS. The consequences to regional air quality would be localized for both the 1-hour and peak hydrogen chloride Air Force standard (exceedance out to 6.5 kilometers [4 miles] and 7 kilometers [4.3 miles], respectively beyond the KLC boundary) and would be of a short duration. Due to the highly unlikely potential for a dual accident, the localized short term nature of the air quality exceedence, and the conservative nature of the modeling data inputs, the impact to regional air quality is considered minor.
Post-Launch Activities

Post-launch activities would include the removal of all mobile assets brought to KLC. This removal could result in small localized amounts of PM-10, which would have only minor impacts to air quality.

4.1.1.2.3 In-Flight Interceptor Communication System Data Terminal

Construction

Alternative 1 would require the construction of one IDT (among three alternative sites), one COMSATCOM (among four alternatives), and connecting roads. The greatest emissions would be during site preparation activities that include grubbing and clearing of vegetation, site grading and stockpiling of soil and select fill materials. The largest of the IDT sites would require approximately 5.9 hectares (14.6 acres) of land to be disturbed, and one COMSATCOM site would disturb 2.8 hectares (7.0 acres). Potential construction emissions for both the largest IDT site and one COMSATCOM are listed in table 4.1.1-15.

<table>
<thead>
<tr>
<th>Emission</th>
<th>Year 1 metric tons (tons)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Carbon Monoxide</td>
<td>0.72 (0.79)</td>
</tr>
<tr>
<td>Oxides of Nitrogen</td>
<td>3.30 (3.60)</td>
</tr>
<tr>

<td>0.51 (0.57)</td>
</tr>
<tr>
<td>Oxides of Sulfur</td>
<td>0.23 (0.25)</td>
</tr>
<tr>
<td>PM-10</td>
<td>20.5 (23.0)</td>
</tr>
</tbody>
</table>

Construction activities for IDT and COMSATCOM facilities could produce approximately 41 metric tons (46 tons) of PM-10. It is anticipated that this PM-10 volume would be reduced by half to 20.5 metric tons (23 tons) through implementation of Best Management Practices for dust suppression during site preparation activities. Only minor impacts would be anticipated to air quality from construction activities. Site preparation activities would be relatively short in duration affect a relatively small footprint, and would employ a variety of Best Management Practices.

Operation

Operation of the IDT and COMSATCOMs would have little effect on regional air quality. Power would be provided by offsite commercial power sources, however in the event of loss of power a 275 kW diesel generator would be utilized along with the 3,785-liter (1,000-gallon) AST for fuel. Emissions produced during the generator’s limited operation are listed in table 4.1.1-6. These levels of emissions would not be expected to impact regional air quality. The generator would be tested weekly during non-launch periods and during power outages, approximately 250 hours a year. Use of this generator would require an amendment to the existing Pre-approved Limit Permit.
Personnel associated with the IDT and COMSATCOMs would be included in the up to 235 personnel needed to support a dual interceptor launch and would not cause an additional air quality impact.

4.1.1.2.4 Sensors

Construction

Alternative 1 would utilize an existing gravel pad area for mobile telemetry and would not require new construction; therefore there would be no air quality impacts.

Operation

Operation of the mobile telemetry would have a minor impact on the regional air quality. Power would be provided by two 10-kW generators for the mobile telemetry. Anticipated emissions from the use of these generators would be for a 1-week period, up to five times per year. Table 4.1.1-6 lists the possible emissions from use of the generators. Use of these generators would require an amendment to the existing Pre-approved Limit Permit.

4.1.1.2.5 TPS-X

Construction

The installation of the TPS-X at KLC would require the construction of a pad for the 38- by 58-meter (125- by 190-foot) hardstand and disturbance of approximately 0.3 hectare (0.8 acre). The potential TPS-X location would be the same as for the potential IDT site south of the Loran-C Station. Table 4.1.1-16 lists estimated emission levels of carbon monoxide, oxides of nitrogen, volatile organic compounds, oxides of sulfur and PM-10.

<table>
<thead>
<tr>
<th>Emission</th>
<th>Year 1 metric tons (tons)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Carbon Monoxide</td>
<td>0.039 (0.043)</td>
</tr>

<td>Oxides of Sulfur</td>
<td>0.012 (0.013)</td>
</tr>
<tr>
<td>PM-10</td>
<td>0.77 (0.85)</td>
</tr>
</tbody>
</table>

It is anticipated that the volume of PM-10 produced during construction would be reduced by half through the implementation of Best Management Practices for dust suppression during site preparation activities.

Operation

The prime power unit for the TPS-X at KLC would be a 1.5-MW generator that would provide power to the radar during testing. The generator is assumed to be in operation for 3 weeks (24 hours a day, 7 days a week) five times a year during launch activities. The total time of operation is estimated at a maximum of 2,520 hours per year. Potential generator emissions for
the TPS-X are listed in table 4.1.1-6. Use of this generator would require an amendment to the existing Pre-approved Limit Permit.

4.1.1.3 Alternative 2

4.1.1.3.1 Targets
Target activities associated with Alternative 2 would be similar to those of Alternative 1.

Construction
Construction would include a total disturbed area of 10.5 hectares (26 acres), the same as identified for Alternative 1. Construction impacts would be as described for Alternative 1.

Operation
Operation impacts from pre-launch, launch, and post-launch activities of target launches in Alternative 2 would be similar to those described for target launches in Alternative 1 in section 4.1.1.2.2.

4.1.1.3.2 Sensors
Effects from construction and operation of a mobile telemetry at KLC for Alternative 2 would be the same as described for the sensors of Alternative 1 in section 4.1.1.2.4.

4.1.1.4 Alternative 3
Alternative 3 would include all aspects of Alternative 1. Because Alternative 1 includes GBIs, targets, and all associated facilities, the construction and launch impacts for Alternative 3 would be as described for Alternative 1.

4.1.1.5 Cumulative Impacts
Due to the limited industrialization of Kodiak Island and the surrounding environment, the potential cumulative impacts to air quality due to the proposed interceptor and target facility construction and launches would not be substantial. No other construction is anticipated to occur at the same time as the proposed construction activities. The KLC EA indicated no significant impacts to air quality as a result of nine annual launches and that impacts do not accumulate with multiple launches (Federal Aviation Administration, 1996). It is not likely that the Proposed Action of up to five launches (GBI and/or target) in conjunction with other currently planned or anticipated launches at KLC would exceed nine launches per year, the level of activity analyzed in the KLC EA.

Dual launches of either interceptors or targets would result in increased exhaust emissions compared to a single launch. However, the emissions would disperse quickly and the overall air quality would continue to remain within NAAQS and Alaska AAQS. Proposed activities along with current activities at KLC, including the use of three standby generators, are not anticipated to result in cumulative impacts to air quality.
4.1.1.6 Mitigation Measures
No air quality mitigation measures are proposed for the GMD ETR activities at KLC.

4.1.2 AIRSPACE—KODIAK LAUNCH COMPLEX
Site preparation activities for interceptor, target missiles, IDT, or the TPS-X would have no impact on controlled or uncontrolled airspace, special use airspace, en route airways and jet routes, or airfields and airports in the ROI. Since site preparation activities would not restrict a clear view of runways, helipads, taxiways, or traffic patterns from the airport air traffic control tower, decrease airport capacity or efficiency, affect future VFR or IFR, or affect the usable length of an existing or planned runway, they would also not constitute an obstruction to air navigation.

Potential impacts from flight test activities are discussed below for each alternative.

4.1.2.1 No Action Alternative

Missile Defense Agency
Under the MDA’s No Action Alternative, launches would continue to occur at KLC although the GMD ETR would not be established and GBI and target launch scenarios would not be tested under more operationally realistic conditions. The use of KLC for flight preparation and launches has been analyzed in the North Pacific Targets Program EA (U.S. Army Space and Missile Defense Command, 2001b), the KLC EA (Federal Aviation Administration, 1996) and two U.S. Air Force documents (U.S. Department of the Air Force, 1997a; 2001). These documents concluded that close coordination with the FAA would result in no adverse effects to airspace from launches at KLC.

Under the MDA’s No Action Alternative, KLC would continue to conduct up to nine launches per year through September 2003 as specified in the current launch site operator license. The current license is scheduled for renewal in September 2003. The new license, if issued would outline the terms under which launches would be conducted at KLC. The renewal period would be for another 5 years.

Federal Aviation Administration
Under the FAA’s No Action Alternative, the launch site operator license for KLC would not be renewed and no launches would be allowed to occur from KLC after September 2003. Therefore, there would be no impacts to airspace from launches at KLC.

4.1.2.2 Alternative 1
Potential airspace impacts from implementation of the Proposed Action include the following activities:

- Potential impacts to controlled and uncontrolled airspace
- Potential impacts to existing special use airspace
- Potential impacts to en route airways and jet routes
- Potential impacts to airports and airfields
Controlled and Uncontrolled Airspace

The ROI, located in international uncontrolled class G airspace, has no formal airspace restrictions governing it. Before launching the GBI or target missile from KLC, NOTAMs would be sent in accordance with FAA protocols and DoD requirements. The U.S. NOTAM System, Sections 3-2n(1)(a) and (b), deals with operations/exercises over the high seas, host nation territory, international airspace, and bare-base locations, and specifies the International NOTAM office coordination requirements and procedures as per U.S. Army Regulation 95-10, Department of Defense Notice to Airmen (NOTAM) System, 1 January 1997.

To satisfy airspace safety requirements in accordance with DoD requirements, the KLC Range Safety Officer would obtain approval from the Administrator, FAA. Provision would be made for surveillance of the affected airspace. In addition, safety regulations dictate that launch operations would be suspended when it is known or suspected that any unauthorized aircraft have entered any part of the surface danger zone until the unauthorized entrant has been removed or a thorough check of the suspected area has been performed. When the probability is less than 1x10^-7 that an aircraft would be in an unsafe proximity to the GBI or target missile, the Range Safety Office may establish segmented safety zones to allow for some unrestricted air routes under the flight path during the launch window.

If the TPS-X radar is located at KLC, EMR hazard zones would be established. The potential interference distances are shown in figure 2.3.1-8. The personnel exclusion area would extend for 150 meters (492 feet) in front of the radar. The FAA would be requested to establish a navigation warning advising aircraft to remain at least 1,500 meters (4,900 feet) from the TPS-X radar site during use. EEDs in the presence and shipping phase, such as a missile mounted on an aircraft, would need to be at least 800 meters (2,625 feet) from the radar. EEDs on the ground in the handling phase would need to be at least 400 meters (1,312 feet) from the radar due to potential sidelobe exposure. The interference areas are directional, and would be centered on the launch azimuth, between 135 degrees and 225 degrees.

A visual survey of the area would be conducted to verify that all personnel are outside the hazard zone before startup. Personnel may not enter these hazard zones while the radar is in operation. The radar is prevented from illuminating in a designated cutoff zone, in which operators and all other system elements would be located. Potential safety consequences associated with radar interference with other electronic and emitter units (flight navigation systems, tracking radars, etc.) would also be examined before startup. Adherence to AADC, FAA, and DoD safety procedures relative to radar operations would preclude significant impact to airspace.

Special Use Airspace

There is no special use airspace in the KLC ROI, and as such there would be no impact on airspace from proposed program activities.

En Route Airways and Jet Routes

Coordination between KLC and the controlling airspace agencies (Anchorage and Oakland ARTCC) would minimize potential impacts to the commercial air corridors entering and exiting Kodiak Airport north of KLC (figure 3.1.2-1), and the flexible tracks south of KLC that are used to transition to the North Pacific route system.
Airports and Airfields
The proposed activities in Alternative 1 would not restrict access to, nor affect the use of, existing airfields and airports in the ROI.

4.1.2.3 Alternative 2
The proposed activities at KLC under Alternative 2 would be similar to those described under Alternative 1. Alternative 2 involves launching only target missiles, but the potential impacts to airspace would be the same.

4.1.2.4 Alternative 3
Alternative 3 would include all aspects of Alternatives 1 and 2. Because Alternative 1 includes GBIs, targets, and all associated facilities, the construction and flight impacts for Alternative 3 would be as described for Alternative 1.

4.1.2.5 Cumulative Impacts
There is no airspace segregation method such as a warning or restricted area to ensure that international airspace would be cleared of nonparticipating aircraft. However, missile launches are short-term, discrete events. The KLC EA concluded there would be no cumulative impact to airspace for nine annual launches (Federal Aviation Administration, 1996). It is not likely that the Proposed Action of up to five launches (GBI and/or target) in conjunction with other currently planned or anticipated launches at KLC would exceed nine launches per year, the level of activity analyzed in the KLC EA. The use of the required scheduling and coordination process for international airspace and adherence to applicable DoD directives and U.S. Army regulations concerning issuance of NOTAMs and selection of missile firing areas and trajectories further reduce the potential for incremental, additive, cumulative impacts.

4.1.2.6 Mitigation Measures
The required coordination procedures with the FAA and scheduling requirements of KLC minimize any potential impacts so that no mitigation measures have been identified as necessary for the GMD ETR proposed activities. NOTAMs would be sent in accordance with FAA protocols and DoD requirements.

4.1.3 BIOLOGICAL RESOURCES—KODIAK LAUNCH COMPLEX
The biological resources analytical approach involved evaluating the potential impacts of the Proposed Action and alternatives, such as construction, site preparation activities, use of existing and new sensors, and missile launches, on vegetation, wildlife, threatened and endangered species, and sensitive habitat within the ROI. Impacts that could result from construction and other site preparation activities include disturbance and removal of vegetation and disturbance to wildlife from the accompanying noise and presence of personnel. Impacts could also result from launch-related activities such as noise, air emissions, debris impacts, and the use of radar equipment.
Criteria for assessing potential impacts to biological resources are based on (1) the number or amount of the resource that would be impacted relative to its occurrence at the project site, (2) the sensitivity of the resource to proposed activities, and (3) the duration of the impact. Impacts are considered substantial if they have the potential to result in reduction of the population size of federally listed threatened or endangered species, degradation of biologically important unique habitats, substantial long-term loss of vegetation, or reduction in capacity of a habitat to support wildlife.

All transportation of equipment and materials such as fuels would be conducted in accordance with applicable federal (DOT) and state regulations. Hazardous materials would be inspected prior to accepting a shipment. Bulk hazardous materials drums would be stored in approved containers during transportation that meet National Fire Protection Association industrial fire protection codes and required containment systems. Spill response materials such as sorbents, drain covers, mops, brooms, drum repair materials and tools, warning signs and tapes, and personal protective equipment would be readily available for use in the event of an unplanned release of hazardous materials. These SOPs for spill prevention, containment, and control measures while transporting equipment and materials would preclude impacts to biological resources.

GMD ETR program personnel would remove all mobile equipment/assets brought to the installation at the conclusion of its testing activities. Transportation for removal of equipment would be the same as when it was brought into the installation. These activities would result in impacts similar to, but less than, those caused by site preparation. All mobile assets would be located on existing gravel pads at KLC.

4.1.3.1 No Action Alternative

Missile Defense Agency

Under the MDA’s No Action Alternative, launches would continue to occur at KLC, although the GMD ETR would not be established and GBI and target launch scenarios would not be tested under more operationally realistic conditions. KLC would continue to provide ongoing support to single Strategic Target System launches from the GMD Element; however, test scenarios would be severely limited. The KLC EA (Federal Aviation Administration, 1996) indicated no significant impact to biological resources from nine annual missile launches. The North Pacific Targets Program EA (U.S. Army Space and Missile Defense Command, 2001b) determined that no significant impacts would occur to biological resources as a result of launching a Strategic Target System Missile. The Strategic Target System launches would continue to be managed within the nine launches previously analyzed in the KLC EA (Federal Aviation Administration, 1996) and no additional impacts to biological resources would be expected to occur.

Federal Aviation Administration

Under the FAA’s No Action Alternative, the launch site operator license for KLC would not be renewed, and no launches would be allowed to occur from KLC after September 2003. Therefore, there would be no impacts to biological resources from launches at KLC.
4.1.3.2 Alternative 1

4.1.3.2.1 Ground-Based Interceptors

Construction

Vegetation

The proposed activities under Alternative 1 would require construction as described in section 2.3.1.1. No significant impacts to vegetation are anticipated, since new construction would occur mainly in upland areas of hairgrass-mixed forb meadow, one of the predominant vegetation types at KLC. This loss of vegetation (approximately 14 hectares [36 acres]) would represent only a small portion of the total vegetation available within KLC boundaries and the adjacent region.

Threatened and Endangered Plant Species. No federally proposed or listed candidate, threatened, or endangered plant species have been observed within the boundaries of KLC. Therefore, there would be no impacts to listed plant species.

Wildlife

Impacts from ground disturbance and equipment noise could include loss of habitat, displacement of wildlife, increased stress to wildlife, and disruption of daily or seasonal behavior. As stated above, new construction would occur mainly in upland areas of hairgrass-mixed forb meadow, one of the predominant vegetation types at KLC. Additional habitat for those species that could potentially be displaced is located adjacent to those areas proposed for disturbance. Site preparation activities would not result in impacts to Essential Fish Habitat since no water bodies would be affected.

Noise rather than the sight of machines appears to cause more disturbance to wildlife. The effects of noise on wildlife vary from serious to no effect in different species and situations. Behavioral responses to noise also vary from startling to retreat from favorable habitat, due partly to the fact that wildlife can be very sensitive to sounds in some situations and very insensitive to the same sounds in other situations (Larkin, 1996). Since there are no absolute standards of short-term noise impacts for potentially noise-sensitive species, a short-term maximum noise exposure of 92 dB was suggested as a significant cut-off for impacts in a noise monitoring study for the HEDI I missile (U.S. Army Strategic Defense Command, 1989b; 1990). This noise level is equivalent to being 1 meter (3 feet) from a power lawnmower. This noise level is similar to the range of 80 to 90 dBA defined as known to disturb waterfowl and wildlife in the KLC EA (Federal Aviation Administration, 1996).

Typical noise levels at 15 meters (50 feet) from construction equipment range from 70 to 98 dBA. Wildlife is known to exhibit a startle response when exposed to short-term noise impacts. The combination of increased noise levels and human activity would likely displace some small mammals and birds that forage, feed, nest, or have dens within this 15-meter (50-foot) radius. However, sufficient foraging and feeding habitat occurs in adjacent areas. Studies (U.S. Department of the Air Force, 1997) indicate that birds usually show signs of disturbance, such as fluttering of wings, when a noise event occurs, but quickly return to normal behavior after the event. Although construction activities could cause flushing (birds suddenly flying up), this is a common reaction to sudden natural sounds that only slightly increases the energy expenditure of individual birds. Some wildlife may leave the area permanently, while others may likely
become accustomed to the increased noise and human presence. Construction is therefore not expected to have a long-term significant adverse effect on wildlife.

**Threatened and Endangered Wildlife Species.** Disturbance from site preparation activities would be restricted mainly to areas within 15 meters (50 feet) from the construction site. The closest federally endangered Steller sea lion haulout area, approximately 5 kilometers (3 miles) away on Ugak Island, would not be affected by site preparation noise. Federally threatened Steller’s eiders and endangered short-tailed albatross offshore would also be outside the range of the highest site preparation noise levels and are not anticipated to be affected.

**Environmentally Sensitive Habitat**

Wetlands can be impacted both directly and indirectly. Direct impacts can result from filling, dredging, or flooding. Indirect impacts can be caused by disturbance to adjacent land that results in degradation of water quality from chemical or sedimentary runoff. Given the lack of practicable alternative sites in combination with the measures taken to minimize wetland impacts, compliance with Executive Order 11990, *Protection of Wetlands*; DOT Order 5660.1A, *Order on Preservation of the Nation’s Wetlands*; and FAA Order 1050.1D, *Policies and Procedures for Considering Environmental Impacts* has been demonstrated.

Most new construction required for the Proposed Action would be located in upland areas. Construction of the GBI launch silos or launch pad and perimeter fencing around the launch area could disturb approximately 0.6 hectare (1.6 acres) of palustrine, emergent, persistent, seasonally flooded wetlands and 0.2 hectare (0.4 acre) of palustrine, scrub/shrub, broad-leaved deciduous, saturated wetlands (figure 4.1.3-1). The fence line layout is preliminary and could likely be altered before construction to avoid the wetlands. Indirect disturbance to wetlands would be minimized by implementing appropriate techniques to control runoff and other Best Management Practices discussed below.

The following examples of Best Management Practices for soil erosion control that AADC applies during construction activities would further minimize impacts to wetlands:

- Site preparation—vegetation preservation and protection, topsoil preservation, dust control, and temporary gravel construction entrance and exit
- Surface stabilization—temporary and permanent seeding and use of mulches and fabric and gravel blankets
- Runoff control and conveyance measures—installation of diversions, dikes, grassed waterways, and temporary slope drains
- Sediment barriers—straw bale and rock barriers, sediment fences
- Sediment traps and basins
- Stream protection—temporary stream crossings and streambank stabilization
- Protection of soil and fill storage piles

(Federal Aviation Administration, 1996)
Wetlands Within the Kodiak Launch Complex and Proposed Facility Locations
Kodiak Island, Alaska

Figure 4.1.3-1
SOPs mentioned above for spill prevention, containment, and control measures while transporting equipment and materials would also preclude impacts to wetlands. Steller sea lion critical habitat is outside the area that could be impacted by site preparation activities.

**Operation**

Dual launch activities could potentially occur. Dual launches could result in a slightly larger affected area and longer duration of disturbance to wildlife. Impacts would in some cases be slightly greater than, but similar, to those analyzed below for single launches.

**Vegetation**

Normal GBI launch activities are not expected to significantly impact vegetation. Blast residue would be contained within the silo or close to the launch site in case of a pad GBI launch, minimizing the potential for impacts on vegetation. Launch exhaust products would include hydrogen, hydrogen chloride, aluminum oxide, carbon dioxide, carbon monoxide, nitrogen, water, and chlorine. Nominal launch activities during dry conditions could result in the deposition of very small amounts of aluminum oxide from missile exhaust. Most of this aluminum oxide would be suspended in air and dispersed over extremely large areas; the amount deposited would have little effect. As stated in the air quality section, the concentration levels of exhaust products from a dual launch would be approximately double those of a single launch. Under natural conditions, the chemical is not a source of toxic aluminum; the EPA has determined that non-fibrous aluminum oxide as found in solid rocket motor exhaust is nontoxic (U.S. Department of the Air Force, 1997a). Analysis of launch-related deposition of aluminum oxide after six launches from KLC has not shown it to be harmful to vegetation (Alaska Aerospace Development Corporation, 2002b).

The greatest potential for impacts to vegetation comes from hydrogen chloride deposition. Direct effects could include discoloration, foliage loss, and changes in species composition. Rain within 2 hours of a launch could cause hydrogen chloride to be deposited in small quantities. This chemical, when emitted during solid missile launches for very large flight vehicles (such as the Space Shuttle), is known to injure plant leaves and affect wildlife. However, the potential effect on vegetation from the proposed launches of the much smaller GBIs is expected to be slight. Observation of plant communities at other launch sites such as KTF, Cape Canaveral, and Vandenberg AFB indicate that vegetation continues to thrive in the immediate areas within 150 to 240 meters (492 to 787 feet) of the launch pads. Vegetation sampling conducted in the area near active launch pads at KTF has not indicated that hydrogen chloride emissions from launches conducted during the last 20 years resulted in any lasting effects (U.S. Army Space and Strategic Defense Command, 1993a). No obvious additional needle loss or browning of vegetation adjacent to the launch site has been documented through six launches from KLC (Alaska Aerospace Development Corporation, 2002b).

**Threatened and Endangered Plant Species.** No federally listed candidate, threatened, or endangered plant species have been observed within the boundaries of KLC.

**Wildlife**

**Noise.** Potential noise effects on wildlife can be categorized as auditory and non-auditory. Auditory impacts to marine mammals would consist of injury effects such as eardrum rupture or behavioral impairments such as temporary threshold shift (TTS). Non-auditory effects could
include stress, behavioral changes, and interference with mating or foraging success. The effects of noise on wildlife vary from serious to no effect in different species and situations. Behavioral responses to noise also vary from startling to retreat from favorable habitat. Animals can also be very sensitive to sounds in some situations and very insensitive to the same sounds in other situations. (Larkin, 1996) Informal observation at several launch facilities indicates the increased presence of personnel immediately before a launch tends to cause birds and other mobile species of wildlife to temporarily leave the area that would be subject to the highest level of launch noise. Therefore, no direct physical auditory changes are anticipated.

Wildlife is known to exhibit a startle effect when exposed to short-term noise impacts, such as the launch of a missile. Video camera observations of a wood stork colony located 0.8 kilometer (0.5 mile) south of the Space Shuttle launch pad at Kennedy Space Center showed that birds flew south away from the noise source and started returning within 2 minutes, with a majority of individuals returning within 6 minutes (National Aeronautics and Space Administration, 1997). A rookery at Kennedy Space Center used by wood storks and other species of wading birds located approximately 750 meters (2,461 feet) from a Space Shuttle launch pad continues to be used successfully, even though it has received peak noise levels of up to approximately 138 dB. (American Institute of Aeronautics and Astronautics, 1993) Birds within 250 meters (820 feet) of Titan launch complexes at Cape Canaveral Air Station have shown no mortality or reduction in habitat use. Titan IV vehicles produce noise levels of approximately 170 dB in the immediate vicinity of the launch pad. This attenuates to 125 dB at a distance of 3 kilometers (2 miles) within about 30 seconds following launch. (U.S. Department of the Air Force, 1990b) Noise from Minuteman launches ranges from 98 dBA approximately 4.2 kilometers (2.6 miles) from the launch site to 80 dBA approximately 13 kilometers (8 miles) from the launch site (U.S. Department of the Air Force, 1999). The level of noise for the GBI missile during launch and flight is expected to be less (similar to the 94 dB at 3.0 kilometers [2 miles] from the launch site analyzed in the KLC EA for the Castor 120™) and relatively short in duration.

The KLC EA concluded that, although birds within a 9.7-kilometer (6-mile) radius of the launch pad could be exposed to noise levels above 83 dBA, impacts to birds from launch-related noise would not be severe and would be limited to startle reactions (Federal Aviation Administration, 1996). Peak noise levels in the vicinity of Narrow Cape would be nearly instantaneous, and the entire noise event would last less than 60 seconds. According to monitoring results from the prior six KLC launches, bald eagle habitat use appears to have been unaffected. The Narrow Cape bald eagle nest, which is downrange of the current launch pad, was seasonally occupied and productive during the monitoring period. (Alaska Aerospace Development Corporation, 2002b) Any indication of disturbance to eagle nesting or nesting behavior would be reported immediately to the KLC launch point of contact as specified in the Natural Resources Management Plan (NRMP).

A Biological Opinion (Federal Aviation Administration, 1998) prepared for the FAA and AADC addressed the potential for impacts on the Steller’s eider and short-tailed albatross as a result of operation of the KLC. Interceptor launches would be infrequent, up to five per year over a period of 10 years. Five annual GBI launches would fall within the parameters previously analyzed for KLC and are also not likely to adversely affect listed species. Disturbance to wildlife from single or dual GBI launches would be brief and is not expected to have a lasting impact nor a measurable negative effect on migratory bird populations. Waterfowl would quickly resume feeding and other normal behavior patterns after a launch is completed. Waterfowl driven from preferred feeding areas by aircraft or explosions usually return soon after the
disturbance stops, as long as the disturbance is not severe or repeated (Federal Aviation Administration, 1996).

No evidence has indicated that serious injuries to wildlife have resulted from prior launches, and no long-term adverse effects are anticipated. The brief noise peaks produced by the GBI are comparable to levels produced by close range thunder (120 dB to 140 dB peak). There is no species known to be susceptible to hearing damage following exposure to this noise source (U.S. Department of the Air Force, 2001).

**Emissions.** The KLC area has a high level of rainfall and short steep streams, and small amounts of deposition from launches would be quickly flushed from stream drainages. No long-term impacts to fish in streams or Essential Fish Habitat within the ROI are expected.

Hydrogen chloride, which is emitted during missile launches, is known to affect wildlife. Birds flying through the exhaust plume may be exposed to concentrations that could irritate eye and respiratory systems (Federal Aviation Administration, 1996). However, results of a monitoring program conducted following a Strategic Target System launch from KTF in Hawaii indicated little effect upon wildlife due to the low-level, short-term hydrogen chloride emissions (U.S. Army Space and Strategic Defense Command, 1993a). The program included marine surveys of representative birds and mammals for both pre-launch and post-launch conditions. Studies on representative birds and mammals reviewed in the Final EIS for the Strategic Target System (U.S. Army Strategic Defense Command, 1992) also indicated that low-level, short-term exposure to hydrogen chloride would not adversely affect threatened or endangered species or other wildlife. Aluminum oxide and hydrogen chloride do not bioaccumulate; therefore, no indirect effects to the food chain are anticipated.

**Debris.** In the unlikely event of a launch mishap during single or dual launches, scattered pieces of burning propellant could enter coastal water and potentially affect seabirds, Essential Fish Habitat, and pinnipeds hauled out along the adjacent coastline. Unburned solid fuel is hard and rubber-like, and any ammonium perchlorate would dissolve slowly out of the rubber-like binder, producing ammonia and chlorine that would disperse into the marine waters. Were hazardous materials to leach out of the intercept debris, the great volume of water in the ocean would dilute the contaminant to acceptable levels. The solid fuel’s aluminum oxide is insoluble; in addition, as the fuel slowly dissolves, its outer layers become spongy, further retarding dissolution. Thus, no toxic levels of ammonia, chlorine, or aluminum would be expected. A recent study conducted for the U.S. Air Force (Lang, et al., 2001) measured the amount of perchlorate lost from solid propellant samples immersed in fresh and salt water. From the measurement of the concentration of the perchlorate ion in solution, the mass fraction loss of the propellant sample due to perchlorate leaching was calculated. The results are presented in the KLC Water Resources section, table 4.1.14-2. As shown in the table, it would take approximately 270 days for 90 percent of the perchlorate to leach out of solid propellant that lands in the ocean (at 29°C [84°F]). The perchlorate would be expected to be diluted as it mixes with the surrounding water.

The potential impact to Essential Fish Habitat from nominal launch activities (single and dual) would mainly be from missile debris to waters off the coast. Although debris could affect individuals close to the surface, overall species’ population would not be substantially impacted. The Pasagshak River would not be affected by nominal launch activities and is outside the area likely to be affected by a launch anomaly. Anadromous and marine fisheries would not be
affected by proposed launch activities. Concentrations of toxic materials would be highest in this shallow water and have a greater chance of being ingested by feeding animals. However, the potential for a launch mishap is relatively slight, and in most cases the errant missile would be moving at a rapid rate such that pieces of propellant and other toxic debris would strike the water further downrange. The debris would also be widely scattered, which would reduce the possibility of ingestion. The number of individuals injured or killed would not likely affect overall species’ populations. (U.S. Department of the Air Force, 2001)

Debris impact and booster drops in the BOA off the coast are not expected to adversely affect marine mammal species protected by the Marine Mammal Protection Act of 1972. An early flight termination or mishap could result in debris impact along the flight corridor. Early flight termination could result in widely scattered debris, but the probability of this debris hitting wildlife is remote.

Fire from an early flight termination could impact terrestrial wildlife near the launch site. However, emergency fire-fighting personnel would be on stand-by status for all launch activities as a protective measure.

**Threatened and Endangered Wildlife Species.** The closest Steller sea lion haul-out sites are at Ugak Island, approximately 5 kilometers (3 miles) southeast of KLC, and Gull Point, approximately 16 kilometers (10 miles) southwest of KLC. Ugak Island is used seasonally by the Steller sea lion during the late summer to early fall postbreeding period (Alaska Aerospace Development Corporation, 1999). As addressed in the KLC EA, studies have indicated that launches are likely to produce some level of alarm response in the sea lions using Ugak Island (Federal Aviation Administration, 1996). These responses could range from a heightened state of alertness to total flight of all sea lions from the haulout site.

According to the U.S. Air Force’s QRLV Program EA (U.S. Department of the Air Force, 2001), while it is expected that Steller sea lions hauled out on Ugak Island would react to a launch by entering the water, there is no biologically significant consequence of this behavior because sea lions routinely spend long hours in the water and have been observed returning to land hours later. Since the sea lions do not breed on Ugak Island, there would be no effect on mother–pup bonding. The National Marine Fisheries Service has concurred with the U.S. Air Force’s opinion that predicted launch and overflight noise would have no significant impact on marine mammals. However, AADC has requested a Letter of Authorization from the National Marine Fisheries Service for the incidental harassment take of marine mammals. The USFWS also concurred that no adverse effects would occur to listed species in the ROI of an ait-2 launch. The predicted launch noise level for the GBI would be similar to or less than the level predicted and measured for ait and QRLV launches and as such, no substantial adverse impacts to listed species are expected.

Foraging shorebirds would be subjected to increased energy demands if flushed by the noise, but this should be a short-term, minimal effect. Waterfowl generally show a pronounced startle effect when exposed to noise levels of 95 to 105 dB. It is unlikely that the short-tailed albatross would be impacted by a GBI missile in flight since the trajectory is almost vertical and the missile would reach an altitude of approximately 3,048 meters (10,000 feet) while still over land, approximately 20 seconds after launch.
Although Steller’s eiders rafting off Narrow Cape may be disturbed by the Proposed Action, since they do not breed within the ROI and the disturbance would be minor and infrequent, GBI launches from KLC are not expected to impact breeding or the nesting success of this species.

According to protocol of the KLC Environmental Monitoring Plan, five pre-launch and five post-launch aerial surveys for Steller’s eiders were supposed to be performed for the first five missile launches at KLC. Inclement weather adversely affected this task during all five KLC launches. However, the data collected were sufficient to show that rocket launches were not adversely affecting either species numbers or habitat use patterns of either the eider or of its designated surrogate for monitoring, the harlequin duck (Environment and Natural Resources Institute and Alaska Aerospace Development Corporation, 2002). Steller’s eiders overwinter in the area from mid-October to March. Since it was not known when the launches would take place and if Steller’s eiders would be in the vicinity, the harlequin duck was used as a surrogate during surveys when the eider was not observed in the area. Steller’s eiders were observed during the 1998 ait-1 and 2001 QRLV launches from KLC. No eiders were observed before the ait-1 launch, but 30 were seen minutes after about 0.40 kilometer (0.25 mile) south of Lone Point. The number fluctuated widely during the QRLV monitoring periods. Harlequin ducks were observed during all monitoring periods with no significant differences between pre- and post-launch time periods. Steller’s eider and harlequin duck numbers and use of habitat appeared unaffected by the six prior launches at KLC. (Alaska Aerospace Development Corporation, 2002b)

Environmentally Sensitive Habitat
Nominal GBI launches are not expected to result in impacts to wetlands on KLC. SOPs for spill prevention, containment, and control measures while transporting equipment and materials would also preclude impacts to wetlands.

4.1.3.2.2 Target Missiles
Construction
Vegetation
Alternative 1 would require construction of additional facilities as discussed in section 2.3.1.1. These new facilities would be located adjacent to the proposed GBI silos or launch pad and included within the same fenced area. Existing facilities, such as the existing launch pad, would be modified. No significant impacts to vegetation are anticipated since new construction would occur mainly in upland areas of hairgrass-mixed forb meadow, one of the predominant vegetation types at KLC. This loss of vegetation (approximately 10.5 hectares [26 acres]) would represent only a small portion of the total vegetation available within KLC boundaries.

Threatened and Endangered Plant Species. No federally proposed or listed candidate, threatened, or endangered plant species have been observed within the boundaries of KLC.

Wildlife
Impacts to wildlife from site preparation activities described above under vegetation would be the same as those discussed above for the GBI site preparation.
Threatened and Endangered Wildlife Species. Impacts to threatened and endangered wildlife species from site preparation activities would be the same as those discussed above for the GBI site preparation.

Environmentally Sensitive Habitat
Impacts to environmentally sensitive habitat would be the same as those discussed above for GBI site preparation.

Operation
Dual target launches could potentially occur. Dual launches could result in a slightly larger affected area and longer duration of disturbance to wildlife. Impacts would in some cases be slightly greater than, but nonetheless similar, to those analyzed below for single launches.

Vegetation
As discussed above for GBI launches, observation of plant communities at other launch sites such as KTF, Cape Canaveral, and Vandenberg AFB indicate that vegetation continues to thrive in the immediate areas surrounding launch pads. Vegetation sampling conducted in the area near active launch pads at KTF has not indicated that hydrogen chloride emissions from launches conducted during the last 20 years resulted in any lasting effects (U.S. Army Space and Strategic Defense Command, 1993b). Further studies at KLC have shown no adverse effects to sensitive vegetation following the first six launches (Environment and Natural Resources Institute and Alaska Aerospace Development Corporation, 2002).

Threatened and Endangered Plant Species. No federally proposed or listed candidate, threatened, or endangered plant species have been observed within the boundaries of KLC.

Wildlife
Target missile launches would be infrequent, up to five per year over a period of 10 years. The potential impacts to wildlife from single or dual launches would be similar to those discussed above for GBI launch activities. A Biological Assessment (Federal Aviation Administration, 1998) prepared for the FAA and AADC as part of the construction and operation EA determined that launches of missiles similar to ait, QRLV, and Castor 120™ from KLC are not likely to adversely affect listed species, such as the Steller’s eider and short-tailed albatross, or critical habitat. Five annual launches of the proposed target missiles would fall within the parameters analyzed for KLC and are also not likely to adversely affect listed species.

Using noise contours obtained from the monitoring of actual launches at PMRF and super-imposing them on the launch site at Kodiak Island, a noise level of 54 dBA at 10,699 meters (35,000 feet) is projected for a Strategic Target System launch. However, this information was obtained by noise monitoring in Hawaii (22 degrees north). Air temperature and humidity affect the propagation of noise. The rate of propagation depends on factors such as distance attenuation, ground attenuation, atmospheric absorption, barrier attenuation, wind effects, and temperature gradient effects. Given atmospheric attenuation with correction for temperature and relative humidity, the actual noise impacts, particularly at the longer distances away from the launch site, might be quite different. Inclement weather precluded the use of a helicopter to set up sound monitors on Ugak Island, and thus no sound data was gathered during the
Strategic Target System launch from KLC in 2001. However, the monitoring report (Alaska Aerospace Development Corporation, 2002b) for the Strategic Target System launch concluded that the noise would likely be similar to ait, QRLV, and Athena missile levels of 80 to 90 dB, which would be audible to pinnipeds. The Peacekeeper missile, which would result in the highest noise levels, uses a military version of the Castor 120™ motor that was analyzed in the KLC EA (Federal Aviation Administration, 1996).

**Threatened and Endangered Wildlife Species.** As addressed in the KLC EA, alarm response in the sea lions using Ugak Island could range from a heightened state of alertness to total flight of all sea lions from the haulout site (Federal Aviation Administration, 1996). Using the noise levels modeled for the Strategic Target System launches at PMRF, the maximum noise levels at the haulout sites on Ugak Island would be approximately 81 dBA, which would be below levels known to disturb waterfowl and wildlife. The monitored noise levels at PMRF indicate a level of 54 dBA at 10,668 meters (35,000 feet). This is significantly less than the 69 dBA indicated by modeling. As such, it is possible, although not assumed that actual sound levels at the haulouts would be less than those indicated by modeling. Using noise levels measured during Peacekeeper missile launches at Vandenberg AFB, the maximum noise levels at the haulout sites on Ugak Island would be approximately 97.7 dBA for a single launch and 100.7 for a dual launch. This would be above the 83 dBA level known to disturb wildlife.

No evidence has indicated that serious injuries would result, and no long-term adverse effects are anticipated. Noise from a recent Athena II launch was measured at 101 dBA at the haul-out sites on Ugak Island. The brief noise peaks produced by the Strategic Target System, Peacekeeper target, and other proposed target missiles are comparable to levels produced by close range thunder (120 dB to 140 dB peak). There is no species known to be susceptible to hearing damage following exposure to this noise (U.S. Department of the Air Force, 2001). The predicted launch noise level for the Strategic Target System of 81 dBA would be less than the level predicted and measured for the QRLV-1 (87.2 dBA at Ugak Island) launch and, as such, no substantial adverse impacts to listed species are expected.

To date, no indications of disturbance to the sea lions from survey activities on Ugak Island, which are done in full view of beached sea lions, have been identified. Safety crews and other personnel are briefed on the survey procedures as well as harassment guidelines established by the National Marine Fisheries Service to minimize harassment. The GMD ETR program would adhere to the terms and conditions of the pending harassment/take permit from the National Marine Fisheries Service.

**Environmentally Sensitive Habitat**

Impacts to environmentally sensitive habitat would be similar to those discussed above for GBI launches.

### 4.1.3.2.3 In-Flight Interceptor Communication System Data Terminal Construction

**Vegetation**

The IDT and road at Sites 1, 2, and 3 would require disturbance of approximately 5.9 hectares (14.6 acres) with a fenced area of approximately 3.2 hectares (8 acres). The COMSATCOM
would require a footprint of approximately 0.10 hectare (0.25 acre) within a fenced area of approximately 2.8 hectares (7 acres) to accommodate the COMSATCOM and equipment. The minimal requirements include a concrete base for the COMSATCOM, an all-weather road to the site, and a prepared surface around the site at least 4.6 meters (15 feet) wide.

Construction would occur mainly in upland areas of hairgrass-mixed forb meadow, one of the predominant vegetation types at KLC. This loss of vegetation would represent only a small portion of the total vegetation available within KLC boundaries.

**Threatened and Endangered Plant Species.** No federally proposed or listed candidate, threatened, or endangered plant species have been observed within the boundaries of KLC.

**Wildlife**

Impacts to wildlife from ground disturbance and equipment noise would be similar to those discussed above for GBI site preparation.

**Threatened and Endangered Wildlife Species.** No impacts to threatened and endangered seabirds or marine mammals are anticipated from construction activities at the inland sites proposed for use for the IDT or COMSATCOM.

**Environmentally Sensitive Habitat**

No wetlands or other sensitive habitat would be disturbed during construction and installation of the IDT.

**Operation**

**Vegetation**

No impacts to vegetation would result from operation of the IDT or COMSATCOM.

**Threatened and Endangered Plant Species.** No federally proposed or listed candidate, threatened, or endangered plant species have been observed within the boundaries of KLC.

**Wildlife**

During normal operations, the IDT would not transmit except for a few minutes during annual testing of the equipment and during the GBI flight tests. Given the short duration of transmission, no adverse impacts to biological resources are anticipated. Most operational impacts to wildlife from the IDT would come from security lighting and noise from electrical generators required for the site. The lighting and noise could encourage species less tolerant of these disturbances to avoid the area. Generator noise could range from 80 to 85 dBA at up to 105 meters (344 feet). These noise levels would only occur a couple of hours a week during maintenance activities required for backup generators or continuously if no commercial power is available.
COMSATCOM primary power is from a commercial source with backup power provided by generator. Communication cable to the Launch Control Center would be required. Equipment would be housed in a military van, a small building, or an existing adjacent facility if available.

**Threatened and Endangered Wildlife Species.** No adverse impacts to threatened and endangered wildlife species are anticipated. As stated above, most operational impacts to wildlife from the IDT would come from security lighting and noise from electrical generators required for the site. Generator noise could range from 80 to 85 dBA at up to 105 meters (344 feet), which would not adversely affect species offshore.

*Environmentally Sensitive Habitat*

No adverse impacts to environmentally sensitive habitat are anticipated from security lighting or generator noise due to operation of the IDT and COMSATCOM.

**4.1.3.2.4 Sensors**

There are currently no sensors permanently located at KLC. Proposed sensor use at one location on KLC and at one out of seven alternate sites throughout south-central or southwest Alaska would require that sensors be transported to these locations. An existing disturbed area would be used to minimize the potential for impacts. Mobile sensors necessary to support GMD ETR activities would also be located on existing disturbed areas. No impacts to biological resources are anticipated.

**4.1.3.2.5 TPS-X Radar**

**Construction**

*Vegetation*

Installation of the TPS-X radar would require disturbance to 0.3 hectare (0.8 acre) of land on KLC for placement of a concrete pad. Construction would occur mainly in upland areas of hairgrass-mixed forb meadow, one of the predominant vegetation types at KLC. This loss of vegetation would represent only a small portion of the total hairgrass-mixed forb meadow habitat available within KLC boundaries.

**Threatened and Endangered Plant Species.** No federally proposed or listed candidate, threatened, or endangered plant species have been observed within the boundaries of KLC. Thus no impacts to threatened or endangered species would result from installation of the TPS-X radar.

*Wildlife*

Impacts from ground disturbance and equipment noise could temporarily displace terrestrial wildlife as discussed for GBI site preparation. Additional similar habitat is available on KLC to accommodate roosting, nesting, and feeding needs.

**Threatened and Endangered Wildlife Species.** No impacts to threatened and endangered seabirds or marine mammals are anticipated from construction activities at the inland site proposed for use for the TPS-X radar.
Environmentally Sensitive Habitat
No wetlands or other sensitive habitat would be disturbed during construction and installation of the TPS-X radar.

Operation

Vegetation
Operation of the Prime Power Unit would require refueling operations. The fuel tank would be filled from a fuel truck, as necessary. Impermeable ground covering material and spill containment berms would be placed for containment of fuel during fueling operations. Spill control procedures would be established using KLC’s approved SOPs, and spill control kits would be present at the site in the unlikely event of a fuel leak or spill.

The Cooling Equipment Unit is a closed system, and no emissions of the ethylene glycol solution are planned. However, because of the remote potential for leaks or spills during system hook-up, or the possibility of ruptured hoses or accidental disconnection, impermeable ground cover would be in place as was described for the Prime Power Unit.

Operation of the TPS-X radar would not result in impacts to vegetation since impermeable ground covering material and spill containment berms would be placed for containment of fuel during fueling operations.

Threatened and Endangered Plant Species. No federally proposed or listed candidate, threatened, or endangered plant species have been observed within the boundaries of KLC. Thus no impacts to threatened or endangered species would result from operation of the TPS-X radar.

Wildlife
The Prime Power Unit is a self-contained trailer with a noise-dampening shroud that would minimize the potential for diesel generator noise impacts.

In terms of the potential for EMR impacts to wildlife, the power densities emitted from the TPS-X radar are unlikely to cause any biological effects in animals or birds. The TPS-X radar is not expected to radiate lower than 5 degrees above horizontal, which would preclude EMR impacts to terrestrial species from either operation of the TPS-X radar during flight tests or later during proposed tactical testing.

The potential for main-beam (airborne) exposure thermal effects to birds exists. In terms of the potential for EMR impacts on wildlife, the Final Ground-Based Radar (GBR) Family of Radars EA (U.S. Army Program Executive Office, Global Protection Against Limited Strikes (GPALS), 1993) analyzed potential impacts on wildlife from EMR. This EA determined that several factors significantly reduce the potential EMR exposure for birds and other wildlife. The radar main beam would normally be located at least 2 degrees above horizontal, which limits the probability of energy absorption by surface-oriented wildlife. The radar beam would normally be in motion, making it extremely unlikely that a bird would remain within the most intense area of the beam for any considerable length of time. The size of the beam is relatively small, which further
reduces the probability of bird species remaining within this limited region of space, even if the beam were still. (Ballistic Missile Defense Organization, 2000)

The analysis methods used to evaluate potential effects of RF radiation on birds is the MPEL, which defines the maximum time-averaged RF power density allowed for uncontrolled human exposure (and by extrapolation, to birds and other species). The MPEL method is independent of body size or tissue density being exposed. Analysis conducted during preparation of the GBR EA (U.S. Army Program Executive Office, Global Protection Against Limited Strikes (GPALS), 1993) was based on a conservative approach of limiting the microwave energy absorption rate on the Aplomado falcon (*Falco femoralis*), a bird listed as endangered by the USFWS and the State of New Mexico. The energy absorption rate was based on the falcon remaining continuously within the main beam of the ground-based radar. The absorption rate was then compared to the bird’s resting metabolic rate. The analysis indicated power densities would have to exceed 42 mW/cm² to affect the falcon. Power densities of 38 to 61 mW/cm² have been determined necessary to affect other birds weighing up to 3.5 kilograms (7.7 pounds).

The analyses were based on the conservative assumption that the energy absorption rate of a bird’s body was equal to its resting metabolic rate and that this may pose a potential for an adverse effect. Birds in general typically expend energy at up to 20 times their resting metabolic rates during flight. Since birds are not likely to remain continuously within the radar beam and the power density is not expected to exceed levels stated above that could impact birds, the likelihood of harmful exposure is remote. (Ballistic Missile Defense Organization, 2000)

**Threatened and Endangered Wildlife Species.** The potential for impacts to threatened and endangered seabirds would be the same as that discussed above for wildlife. The TPS-X radar is not expected to radiate lower than 5 degrees above horizontal, and since marine mammals would normally be found below the surface of the water, this signal height would be safely above any surfacing mammals. RF radiation does not penetrate the surface of water to any great degree. The power density level just below the surface of the ocean would not exceed the permissible exposure level for uncontrolled environments. (U.S. Department of the Navy, 2002a) No adverse impacts would occur to whales, other marine mammals, or sea turtles at least 1.3 centimeters (0.5 inch) below the surface. It is also highly unlikely that an individual would be on or substantially above the surface of the water for a significant amount of time within the main beam or side lobe areas when the TPS-X radar would be operating. No impacts to marine mammals offshore are expected as a result of proposed radar operation on KLC since these species would normally be found in the ocean outside the 150-meter (492-foot) personnel exclusion zone. For these reasons, no effects are anticipated on the humpback whale, other marine mammals, or sea turtles that might be present in the vicinity. Therefore, no further action regarding whales is required pursuant to the Endangered Species Act and the Marine Mammal Protection Act.

*Environmentally Sensitive Habitat*

No wetlands or other sensitive habitat would be adversely affected during operation of the TPS-X radar.
4.1.3.3 Alternative 2

No GBI-related construction would be required at KLC under Alternative 2 since GBI launches would occur from Vandenberg AFB and RTS instead of KLC and RTS. Target launch-related impacts would be identical to those described under Alternative 1. As discussed in Alternative 1, proposed sensor use at one location on KLC and at one out of seven alternate sites throughout south-central or southwest Alaska would require that sensors be transported to these locations. Mobile sensors necessary to support GMD ETR activities would be located on existing disturbed areas. No impacts to biological resources are anticipated.

4.1.3.4 Alternative 3

For the purposes of the discussion at KLC, the construction and flight impacts for Alternative 3 would be as described above for Alternative 1.

4.1.3.5 Cumulative Impacts

Construction associated with the GMD ETR program would result in the loss of up to approximately 34 hectares (85 acres) of meadow and shrubland within KLC boundaries. When combined with past disturbed areas the total would equal approximately 52 hectares (128 acres). This cumulative total represents approximately 3.5 percent of the total available acreage of KLC. Similar habitat is available adjacent to the proposed locations and no federally threatened or endangered plants have been identified within KLC boundaries. No cumulative changes in plant community composition or structure have been identified at other active launch locations such as Vandenberg AFB and Kennedy Space Center.

The KLC EA indicated no significant impact to biological resources from nine annual launches (Federal Aviation Administration, 1996). It is not likely that the Proposed Action of up to five launches (GBI and/or target) in conjunction with other currently planned or anticipated launches at KLC would exceed nine launches per year, the level of activity analyzed in the KLC EA. According to the QRLV EA (U.S. Air Force, 2001), multiple failures at the same point in flight during launches would be required to cumulatively affect Essential Fish Habitat or other sensitive biological resources. This scenario is highly unlikely. Combined activities would be performed at different times and locations. No cumulative impacts from launches proposed for the GMD ETR program are anticipated.

4.1.3.6 Mitigation Measures

No biology mitigation measures are proposed for the GMD ETR activities at KLC. GMD ETR proposed activities would adhere to the terms and conditions imposed by the National Marine Fisheries Service on AADC.

4.1.4 CULTURAL RESOURCES—KODIAK LAUNCH COMPLEX

Potential impacts on archaeological and historic resources may result from construction; ground-clearing; off-road traffic activities; sound pressure damage; increased human presence in archaeologically sensitive areas; and/or alteration, modification, renovation, or demolition of existing potentially significant facilities and other activities.
Only those cultural resources determined to be potentially significant under existing legislation are subject to protection from adverse impacts resulting from the Proposed Action or its alternatives. To be considered significant, cultural resources must meet one or more of the criteria established by the National Park Service that would make that resource eligible for inclusion in the National Register. The term eligible for inclusion includes both properties formally determined as such and all other properties that meet the listing criteria. Sites which have not yet been formally evaluated are considered potentially eligible and, as such, are afforded the same consideration as formally nominated properties. Prehistoric (usually referred to as archaeological), historic, or traditional significant cultural resources are referred to as historic properties.

An undertaking is considered to have an effect on a historic property when it may alter characteristics of the property that may otherwise qualify the property for inclusion in the National Register. An effect is considered to be adverse when it diminishes the integrity of the property’s location, design, setting, materials, workmanship, feeling, or association. Adverse effects on historic properties include but are not limited to:

- The physical destruction, damage, or alteration of all or part of the property
- Isolation of the property from, or alteration of the character of, the property’s setting when that character contributes to the property’s qualification for the National Register
- Introduction of visual, audible, or atmospheric elements that are out of character with the property or alter its setting
- Neglect of a property resulting in its deterioration or destruction
- Transfer, lease, or sale of the property

4.1.4.1 No Action Alternative

Missile Defense Agency

Under the MDA’s No Action Alternative, launches would continue to occur at KLC although the GMD ETR would not be established and GBI and target launch scenarios would not be tested under more operationally realistic conditions. These launches could include missions in support of the GMD program. KLC would continue to operate as a licensed launch facility, and, as concluded in the KLC EA (Federal Aviation Administration, 1996), no cultural impacts would be anticipated.

Federal Aviation Administration

Under the FAA’s No Action Alternative, the launch site operator license for KLC would not be renewed and no launches would be allowed to occur from KLC after September 2003. Therefore, there would be no impacts to cultural resources from launches at KLC.
4.1.4.2 Alternative 1

4.1.4.2.1 Ground-Based Interceptors

Construction
The proposed activities under Alternative 1 would require construction of numerous facilities as described in section 2.3.1.1. Potential total disturbed areas due to construction are identified in table 2.3.1-3.

Prehistoric and Historic Archaeological Resources
Previous archaeological surveys have indicated that cultural resources are not present in the upland areas occupied by KLC. As project details are further delineated, additional archaeological surveys may be required to verify the absence of sites within the area of potential effect. Should cultural resources be found during the course of any GMD ETR activity, all activities would cease in the area and the proper authorities would be notified. Subsequent actions would follow the guidance provided; therefore, no impacts to archaeological resources are anticipated.

Large GBI components may need to be brought into KLC by barge, as described in section 2.3.1. Figure 2.3.1-1 shows the proposed barge landing sites. If it is determined that a barge landing is required, one of the three potential sites would be selected for use. At that time, an archaeological survey would be conducted to verify the presence of the reported sites described in section 3.1.4.2 and to determine if there are previously unreported sites within the area of potential effect.

Historic Buildings and Structures
There are no structures in the area currently occupied by KLC infrastructure that are listed on the National Register of Historic Places. No construction activities or building modifications are expected to have an effect on any historic properties.

Native Populations/Traditional Resources
The 1994 survey of the KLC area showed no signs of traditional resources within the ROI. Therefore, no impacts to traditional resources are anticipated. As mentioned above, should cultural resources be found during the course of any GMD ETR activity, all activities would cease in the area and the proper authorities would be notified. Subsequent actions would follow the guidance provided.

Paleontological Resources
There is the potential that shallow-water marine invertebrate fossils would be disturbed during construction of the GBI facilities. However, these fossils are extremely common throughout the areas in and around KLC, and significant impacts to these resources are not anticipated.

Operation
Proposed GBI operations for Alternative 1 at KLC would consist of single and dual interceptor launches.
Flight Activities
Personnel would be informed of the sensitivity of cultural resources and the types of penalties that could be incurred if sites are damaged or destroyed. The only potential impacts to cultural resources would be as a result of debris generated by a test failure. However, the possibility of this occurring is extremely remote.

Post-Flight Activities
Debris recovery from unsuccessful launches at KLC is the responsibility of the user and is closely monitored by AADC. If required, debris recovery on land may involve the use of helicopters and off-road vehicles. Recovery of missile and missile components after unsuccessful launches would be conducted in accordance with KLC procedures. If the potential exists to disturb cultural resources during debris recovery activities, recovery efforts would be coordinated with KLC range representatives and agencies to develop appropriate mitigation measures to avoid impact to sensitive resources and to restore natural areas as necessary following debris recovery efforts.

4.1.4.2.2 Target
Construction
Under Alternative 1, site preparation activities overlap somewhat with GBI facilities. Since no cultural resources have been identified within the construction footprint, there would be no adverse effects to cultural resources due to target facility construction.

Operation
Proposed target operations for Alternative 1 at KLC would include single and dual target launches.

Flight Activities
Target launches, from a cultural resources standpoint, would be similar to an interceptor launch. Personnel would be informed of the sensitivity of cultural resources and the types of penalties that could be incurred if sites are damaged or destroyed. The only potential impacts to cultural resources would be as a result of debris generated by a test failure. However, the possibility of this occurring is extremely remote.

Post-Flight Activities
If required, debris recovery on land may involve the use of helicopters and off-road vehicles. Recovery of missile and missile components after unsuccessful launches would be conducted in accordance with KLC procedures. If the potential exists to disturb cultural resources during debris recovery activities, recovery efforts would be coordinated with KLC range representatives and agencies to develop appropriate mitigation measures to avoid impact to sensitive resources and to restore natural areas as necessary following debris recovery efforts.
4.1.4.2.3 In-Flight Interceptor Communication System Data Terminal

Construction
Under Alternative 1, proposed construction would include disturbance of 8.7 hectares (21.6 acres) for an IDT and COMSATCOM. Cultural resources have not been identified within the areas and therefore there would be no adverse effects to cultural resources from IDT and COMSATCOM construction.

Operation
Proposed activities for Alternative 1 at KLC include IDT and COMSATCOM operations.

Flight Activities
IDT and COMSATCOM operations are not expected to adversely impact cultural resources. The nature of the operation of these systems combined with the lack of existing cultural resources would result in no impacts.

4.1.4.2.4 Sensors

Proposed sensor use at one location on KLC and at one or more out of seven alternate sites throughout south-central or southwest Alaska would require that sensors be transported to these locations. Mobile Systems would likely be parked at pre-existing parking areas and no ground disturbance would be required. Therefore, impacts to cultural resources are not anticipated.

Flight Activities
Operation of sensors of this nature is not expected to produce any short- or long-term effects to cultural resources. Personnel would be informed of the sensitivity of cultural resources and the types of penalties that could be incurred if sites are damaged or destroyed.

4.1.4.2.5 TPS-X

Construction
The installation of the TPS-X at KLC would require the construction of a pad for the 38- by 58-meter (125- by 190-foot) hardstand and disturbance of approximately 0.3 hectare (0.8 acre). The potential TPS-X location would be the same as the potential IDT site south of the Loran-C Station. Previous archaeological surveys have indicated that cultural resources are not present within the upland areas occupied by KLC. As project details are further delineated, additional archaeological surveys may be required to verify the absence of sites within the area of potential effect. Should any culturally related resources be found during the construction of the TPS-X radar, all construction activities would cease and the proper authorities would be notified. Therefore, impacts to cultural resources are not anticipated.

Operation
Operation of the Prime Power Unit would require refueling operations. The fuel tank would be filled from a fuel truck, as necessary. Impermeable ground covering material and spill containment berms would be placed for containment of fuel during fueling operations. Spill
control procedures would be established in accordance with KLC’s approved SPCC SOPs, and spill control kits would be present at the site in the unlikely event of a fuel leak or spill.

The Cooling Equipment Unit is a closed system, and no emissions of the ethylene glycol solution are planned. However, because of the remote potential for leaks or spills during system hook-up, or the possibility of ruptured hoses or accidental disconnection, impermeable ground cover would be in place as was described for the Prime Power Unit.

Because impermeable ground covering and spill containment berms would be employed and due to the lack of located resources in the area, impacts to cultural resources are not anticipated from the refueling of the Prime Power Unit.

In terms of the potential for EMR impacts to cultural resources, the power densities emitted from the TPS-X radar are unlikely to cause any damaging effects to cultural resources. The TPS-X radar is not expected to radiate lower than 5 degrees, which would preclude EMR impacts to terrestrial artifacts from either operation of the TPS-X radar during flight tests or later during proposed tactical testing. Therefore, the operation of the TPS-X radar is not expected to have any adverse impacts to cultural resources.

4.1.4.3 Alternative 2

4.1.4.3.1 Target

Construction

Proposed target construction for Alternative 2 at KLC is identical to that described in Alternative 1.

Operation

Potential impacts from proposed target operations for Alternative 2 at KLC would be identical to that described in Alternative 1.

4.1.4.3.2 Sensors

Construction

The mobilization and setup activities for mobile telemetry systems at remote locations throughout Alaska would be identical to that described for Alternative 1 and would have negligible adverse impacts.

Operation

The operation of mobile telemetry system would be identical to activities described under Alternative 1; however, the system would be operated for target launches only. No operational aspect of the system poses the potential for adverse effects to cultural resources.
4.1.4.4 Alternative 3

Alternative 3 would be identical to Alternative 1 at KLC. Because Alternative 1 includes GBIs, targets, and all associated facilities, the construction and flight impacts for Alternative 3 would be as described for Alternative 1.

4.1.4.5 Cumulative Impacts

The KLC EA indicated no significant impact to cultural resources for nine annual launches (Federal Aviation Administration, 1996). It is not likely that the Proposed Action of up to five launches (GBI and/or target) in conjunction with other currently planned or anticipated launches at KLC would exceed nine launches per year, the level of activity analyzed in the KLC EA. Approximately 17 hectares (43 acres) or 1.1 percent of KLC’s 1,504 hectares (3,717 acres) have previously been disturbed. The proposed action could potentially affect up to 26 hectares (64.2 acres). The cumulative disturbed acreage of the existing and proposed actions would be approximately 43 hectares (106 acres) or 2.9 percent of the total acreage of KLC. No other activities have been identified at KLC that, when combined with the past and proposed action would result in cumulative impacts to cultural resources.

4.1.4.6 Mitigation Measures

No cultural resources mitigation measures are proposed for the GMD ETR activities at KLC at this time. As project details are further delineated, coordination would occur with the Alaska State Historic Preservation Officer to ensure that cultural resources would be protected.

4.1.5 GEOLOGY AND SOILS—KODIAK LAUNCH COMPLEX

The proposed program activities have the potential to increase soil erosion due to construction and vehicle traffic on unpaved roads. GBI and target missile launches could affect the chemical composition of site soils. Construction activities could have a direct short-term affect on the availability of selected geologic resources, such as aggregate for road base and high-strength concrete. Program support facilities, IDT, sensors, radar, and other critical equipment would be potentially subject to strong vibratory ground motions from earthquakes and volcanic ash falls. Active fault segments could potentially result in surface ruptures during large earthquakes resulting in damaging facilities and infrastructure along the trace.

4.1.5.1 No Action Alternative

Missile Defense Agency

Under the MDA’s No Action Alternative, launches would continue to occur at KLC, although the GMD ETR would not be established and GBI and target launch scenarios would not be tested under more operationally realistic conditions. Maintenance or construction projects proposed by AADC at KLC which would result in ground disturbance would be subject to environmental review by the FAA if that action were a modification to the facilities, facility layout, and operations described in the launch site operator license. KLC is located within a seismically active area, but existing facilities have been designed and constructed to Seismic Zone IV standards (Uniform Building Code, 1994) and should withstand probable levels of vibratory ground motion at the site (appendix D). Further, KLC existing facilities are situated at elevations
that are greater than the limits of maximum wave run-up from a probable tsunami event (seismically generated sea wave).

KLC would continue to conduct launches as specified in the KLC launch site operator license. The KLC EA concluded that there would be no measurable long-term changes in the pH of soils from the exhaust deposition of up to nine launches of the Athena-2, using a Castor 120™ motor for propulsion, per year (Federal Aviation Administration, 1996). Environmental monitoring efforts to date have not indicated any adverse changes in soil chemistry resulting from launches. No adverse changes to soil chemistry would be anticipated under the MDA’s No Action Alternative at KLC.

Federal Aviation Administration
Under the FAA’s No Action Alternative, the launch site operator license for KLC would not be renewed and no launches would be allowed to occur from KLC. Therefore, there would be no impacts to geology and soils from launches at KLC.

4.1.5.2 Alternative 1

4.1.5.2.1 Ground-Based Interceptors

Construction
Alternative 1 would require construction of numerous facilities as described in section 2.3.1.1. Fiber optic cable would be pulled through existing conduit in the fiber-optic cable network, however, additional trenching would be required for selected facilities that are proposed outside of the established backbone. The probable area of soil disturbance for all GBI-related facilities and roads would be approximately 14.4 hectares (35.5 acres), owing largely to grubbing and clearing of vegetation within the perimeter fencing, foundation excavation, stockpile, and equipment maneuver areas.

Minor effects to soils are likely to occur because of the proposed site preparation and construction activities. Most proposed facilities and service roads would be situated at or near local topographic highs in mildly sloping terrain, with little potential for sheet flooding or uncontrolled surface water runoff from higher elevations. The upland soils are generally well drained and not considered to be sensitive to erosion on slopes of less than 7 percent (U.S. Department of the Air Force, 2001). AADC would obtain and review necessary definitive information on surface faulting in the vicinity of the proposed GBI facilities. In making final siting and design determinations, AADC would incorporate all appropriate standards specified by its licensed and bonded A&E contractor. The KLC Natural Resource Management Plan (Alaska Aerospace Development Corporation, 1998) would be referred to for managing laydown areas and topsoil piles before construction, and after construction for providing direction on the disposition of excess topsoil and the selection of plants for revegetation. Best Management Practices would be used for erosion and sediment control. Such Best Management Practices could include storm water diversions, sediment barriers, stream protection, dust palliatives, and other stabilization treatments.

Alternative 1 would not significantly deplete sources of construction material in the region. Tertiary bedrock (the Narrow Cape Formation) underlies most of the KLC property and is suitable as general construction fill material and is readily available (Alaska Aerospace
Development Corporation, 1995b). Surface aggregates have previously been hauled from Pasagshak Point to provide surface course materials over the local sandstone. Sources of structural fill material may need to be imported from existing commercial source areas near the City of Kodiak. Indirect short-term impacts could be created from increased dust and traffic.

Operation

Alternative 1 would result in up to five missile launches per year from KLC over the duration of the test program. GBI launch activities may present minor adverse impacts to local soils due primarily to booster stage exhaust emissions during a nominal test launch, or from unburned or partially burned propellant fuels in the event of a terminated flight. Each EKV would contain approximately 7.5 liters (2.0 gallons) of liquid fuel (monomethylhydrazine) and 5.5 liters (1.5 gallons) of liquid oxidizer (nitrogen tetroxide). Preloaded fuel and oxidizer tanks would be installed on the EKV, so there would be no need for onsite fueling of the GBI and thus no anticipated adverse effect from direct contamination of soils from spills at the Missile Assembly Building, GBI silo, or launch pad.

During a nominal launch, the GBI booster would primarily emit hydrogen chloride, aluminum oxide, chlorine, carbon monoxide, carbon dioxide, hydrogen, nitrogen, oxygen, and water. Most hazardous constituents of the propellant would be completely consumed during the launch. Under this scenario, only small amounts of hydrogen chloride and aluminum oxide emissions would be anticipated to directly contact the soil adjacent to the launch pad and downwind of the flight corridor.

No adverse changes to soil chemistry are predicted to occur as a result of hydrogen chloride or aluminum oxide deposition from interceptor launches. As described in section 4.1.1, soil deposition of hydrogen chloride is expected to be minimal because relatively small amounts of hydrogen chloride are released in the booster ground cloud and the emissions disperse rapidly. Because KLC is near the ocean, a significant fraction of the gas phase hydrogen chloride would condense in the marine aerosol (U.S. Air Force, 1997). This would lower the gas phase concentrations, but would also retard the ground deposition and would re-evaporate in several minutes, leaving downwind concentrations unchanged. Deposition of hydrogen chloride was analyzed for the Athena-2 launch vehicle and it was concluded that there would be no measurable increase in soil pH for up to nine launches per year (Federal Aviation Administration, 1996). The Athena-2 (figure 2.1.2-1) uses a Castor 120™ first stage that is larger than the GBI. The proposed GBI configuration (table 4.1.1-10) has less solid rocket fuel capacity than the Athena-2 and, therefore, would likely produce lower exhaust emissions.

Ground deposition of aluminum oxide is expected to be small and result in minor impacts. Soil deposition of measurable levels of aluminum oxide from a moving exhaust cloud is predicted to be negligible (Pacific Missile Range Facility, Barking Sands, 1998). Typically, no solid propellant missile launches would occur during rain, and the launch system would not use a water deluge system for cooling and noise suppression (a deluge system could increase the potential for ground deposition). The EPA has determined that nonfibrous aluminum oxide as found in solid rocket motor exhaust, is nontoxic. (U.S. Army Space and Strategic Defense Command, 1994)

For analysis of dual GBI launches, the exhaust products from a nominal launch are conservatively estimated to be twice the level of a single launch. The analysis of dual launches
under air quality (section 4.1.2.1) concluded that hydrogen chloride emissions would not exceed U.S. Air Force exposure limits and that the level of aluminum oxide would be expected to remain within the non-criteria pollutant level. Therefore, it is not expected that dual launches would result in significant ground deposition of either pollutant.

In the unlikely event of an on-pad fire or catastrophic missile failure over land, most or all of the solid propellant fuel would likely burn up before being extinguished. Any remaining fuel would be collected and disposed of as a hazardous waste. The total quantities of hydrogen chloride and aluminum oxide released in an on-pad failure of a GBI would be equivalent to that released during a nominal launch of an Athena-2. Therefore, an on-pad failure is not expected to result in significant ground deposition of either pollutant.

Small quantities of hydrazine in the EKV could also be released. Hydrazine is heavier than air and, if not oxidized when airborne, would react and/or possibly ignite with the porous earth or would form dimethylamine and oxides of nitrogen. All of these substances are soluble in water. Airborne nitrogen dioxide would return to earth as nitric acid rains in precipitation events. (U.S. Army Space and Strategic Defense Command, 1995)

Likewise, the nitrogen tetroxide that reached the ground would also react with calcium carbonate soil to form calcium nitrates. Calcium nitrate, a strong oxidizer, is a dangerous fire risk in contact with organic materials. Therefore, depending on the amount of the propellant and/or oxidizer released, soils contaminated with these liquid propellants may require removal to prevent subsequent fires or explosions. The relatively small amount of nitrogen tetroxide on the EKV (5.5 liters [1.5 gallons]) would indicate that such a release would pose a relative minor adverse affect on the site and vicinity soils. Calcium nitrate is also water soluble, so it is anticipated that any residual material or unreacted fuel would be washed into surface drainages and directly out to sea.

4.1.5.2.2 Target

Construction

Alternative 1 would require construction of new facilities as described in section 2.3.1.1. In addition, there would be an addition/alteration to an existing launch pad (Launch Pad-1). Most of the adversely affected soil area related to target facilities would be encompassed by GBI site preparation activities.

The environmental considerations and consequences of constructing target facilities at KLC are similar to those discussed for GBI facilities in section 4.1.5.2.1.

Operation

Alternative 1 could result in up to five target missile launches per year from KLC over the duration of the test program. Unlike GBI, target missiles could consist of several different missile types and configurations including Strategic Target System, Minuteman II Target, Peacekeeper Target, and Trident I (C4) Target. All target missiles noted use solid propellants for the booster stage and, as such, during nominal launch scenarios would emit exhaust products from solid fuels at the launch pad and along the flight path. The minor effects to KLC soils anticipated from solid fuel emissions are discussed in section 4.1.5.2.1.
The Peacekeeper Target is the largest of these target vehicles and consists of both solid and liquid fueled stages. For purposes of analysis, Peacekeeper Target also represents the most difficult of the target missiles to handle, store, and refuel. Target missiles would be stored and assembled in missile storage facilities, and liquid fuels and oxidizers would be stored in separate fuel storage facilities. Each of these facilities would have the capability to contain unanticipated releases of liquid fuels, as well as procedures for reacting to such spills to ensure that local soils are not contaminated.

In the highly unlikely event of an on-pad fire or terminated launch, the Peacekeeper Target could potentially release 76,848 kilograms (169,420 pounds) of solid propellant, and 1968 liters (520 gallons) of liquid fuel. As discussed in section 4.1.5.2.1, most of the solid propellant would be expected to burn upon impact with the ground. Unburned components of the fuel would be removed and treated as hazardous waste.

The total quantity of aluminum oxide and hydrogen chloride released in an on-pad failure of a Peacekeeper target would be approximately 26,900 kilograms (59,300 pounds) and (12,300 kilograms (27,100 pounds) respectively. This would be equivalent to that released during three nominal launches of an Athena-2 missile. As discussed in section 4.1.1.2.2, the airborne concentrations of the pollutants would be higher than during a nominal launch, but would return to ambient levels within several hours. Modeling results from the testing of much larger Advanced Solid Rocket Motor program vehicles, which output 196,357 kilograms (432,885 pounds) of aluminum oxide and 115,572 kilograms (254,789 pounds) of hydrogen chloride concluded that there would be no significant impacts to soils as a result of aluminum oxide and hydrogen chloride deposition (National Aeronautics and Space Administration, 1990). Most of the aluminum oxide would be suspended in the air and dispersed over extremely large areas, and the amount of aluminum oxide deposited on the ground would not significantly change the soils chemistry. The hydrogen chloride, under the most conservative rain conditions, would be buffered by the soil and would not significantly change the soil’s pH (National Aeronautics and Space Administration, 1990). The soils in the ROI are expected to have similar alkalinity and a similar buffering capability. Due to the much smaller emission quantities of aluminum oxide and hydrogen chloride from a highly unlikely on-pad accident of a Peacekeeper target, impacts are expected to be minor.

In the highly unlikely case of an on-pad accident, the liquid fuel (hydrazine) from the fourth stage of the Peacekeeper target is heavier than air and, if not oxidized when airborne, would react and/or possibly ignite with the porous earth or would form dimethylamine and oxides of nitrogen. All of these substances are soluble in water. Airborne nitrogen dioxide would return to earth as dilute nitric acid rains in precipitation events. (U.S. Army Space and Strategic Defense Command, 1995)

4.1.5.2.3 In-Flight Interceptor Communication System Data Terminal

Construction

Alternative 1 would require construction of an IDT (one of three optional sites), COMSATCOMs (one of four optional sites), and connecting roads and cables. The probable disturbed area from site preparation would be approximately 5.9 hectares (14.6 acres). Soil disturbance from site preparation activities would be relatively minor and short in duration. Site preparation and construction activities would follow established procedures and Best Management Practices as previously described in section 4.1.5.2.1. AADC would obtain and review necessary definitive
information on surface faulting in the vicinity of the proposed IDT facilities. In making final siting and design determinations, AADC would incorporate all appropriate design standards specified by its licensed and bonded A&E contractor. All IDT facilities would be constructed outside of existing 100-year floodplains and beyond established limits for tsunami wave run-up for a maximum probable tsunami event. Except for localized soil compaction in the construction area, indirect and long-term impacts to the soils resulting from IDT construction would not be anticipated.

Operation
Operation of the IDT would have no direct, short- or long-term effect on surrounding geology or soils. Long-term indirect effects, primarily from vehicle traffic for support and maintenance, would result in very minor soil compaction and dust generation on gravel access roads.

4.1.5.2.4 Sensors
Construction
Alternative 1 would require a single gravel pad area out of seven alternate locations for mobile telemetry. An existing disturbed area would be utilized, and therefore soil disturbance from site preparation activities would be relatively minor and short in duration. Site preparation activities would follow Best Management Practices for soil management and erosion control (see section 4.1.5.2.1).

Operation
Operation of the sensors would have no direct or indirect, short- or long-term effect on surrounding geology or soils. Long-term indirect effects, primarily from vehicle traffic for operational support and maintenance, would result in very minor soil compaction and dust generation on gravel access roads and pads.

4.1.5.2.5 TPS-X Radar
The TPS-X construction and operation requirements and potential impacts to geology and soils would be similar to that described above for the IDT. The alternative location is the same as the potential IDT site south of the Loran-C Station, and the potential impacts would be similar.

4.1.5.3 Alternative 2
4.1.5.3.1 Target
Construction
Under Alternative 2, potential adverse effects to site soils from the construction of new target facilities would be similar to that described for Alternative 1 (see section 4.1.5.2.2).

Operation
Under Alternative 2, target launch operations would be the same as Alternative 1 and would not result in any direct adverse effects on geology and soils at KLC over the short- or long-term.
4.1.5.3.2 Sensors

Construction
Under Alternative 2, potential adverse effects to site soils from the construction of new sensor facilities would be identical to that described for Alternative 1 (see section 4.1.5.2.4).

Operation
Under Alternative 2, sensor operations would be the same as Alternative 1 and would not result in any direct adverse effect on geology or soils at KLC over the short- or long-term.

4.1.5.4 Alternative 3
Alternative 3 would include all aspects of Alternatives 1 and 2. Because Alternative 1 includes GBIs, targets, and all associated facilities, the construction and flight impacts for Alternative 3 would be as described for Alternative 1.

4.1.5.5 Cumulative Impacts
The KLC EA indicated no significant impact to geology and soils from nine annual launches (Federal Aviation Administration, 1996). It is not likely that the Proposed Action of up to five launches (GBI and/or target) in conjunction with other currently planned or anticipated launches at KLC would exceed nine launches per year, the level of activity analyzed in the KLC EA. Missile launches are discrete short-term events. Sampling programs performed during each launch have not shown any accumulation of missile launch exhaust products and therefore, no substantial impacts are anticipated at KLC. Future operations and improvements at KLC would be similar in scope to those described in prior EAs, with the proposed five launches per year being a part of the planned launches at KLC. Minor alteration of soil chemistry and accumulation of contaminants could occur from the exhaust emissions of multiple missile launches at KLC, but such adverse effects would be highly localized and would not pose a hazard to human health. No long-term cumulative impacts are expected from construction and operation at KLC.

4.1.5.6 Mitigation Measures
No specific mitigation measures are proposed. Standard measures for seismic safety would include provision for proper anchoring and/or dampening of missile components and fuel canisters while in storage. Likewise, missile storage buildings and Missile Assembly Buildings would be inspected to ensure structural integrity of foundation, roof, wall connections, and storage racks would be inspected to reduce risk to program personnel during a design seismic event. Before determining the final site layout and design standards for ETR facilities, information bearing on seismic design and construction standards and surface faulting potential would be considered by the design engineer and geotechnical consultant.
4.1.6 HAZARDOUS MATERIALS AND HAZARDOUS WASTE—KODIAK LAUNCH COMPLEX

Potential impacts from hazardous materials would involve their transportation, storage and use. Potential impact from hazardous waste would be related to the generation, accumulation, transportation, and disposal of hazardous wastes used or created in program activities. Impacts relative to hazardous materials and waste are considered significant if they would: (1) increase the potential for exposure to hazardous material or waste; (2) increase the likelihood of a release to the environment; (3) result in noncompliance with applicable regulatory guidelines; or (4) increase the quantities of hazardous materials used or wastes generated beyond available management practices.

Transportation, storage, and use of hazardous materials would be conducted according to applicable OSHA, EPA, DOT, DoD and state regulations and requirements as well as established project and launch complex Standard Safety Operating Plans.

Pollution prevention, recycling, waste minimization, IRPs, USTs, ASTs, asbestos, lead-based paint and PCBs have been evaluated and no impacts were identified. Potential impacts from launch activities are addressed under each alternative as applicable.

4.1.6.1 No Action Alternative

Missile Defense Agency

Under the No Action Alternative, KLC would continue to operate as a commercial launch facility and provide ongoing support to single Strategic Target System launches. The Strategic Target System launches would be managed within the nine launches previously analyzed in the KLC EA (Federal Aviation Administration, 1996), and no hazardous materials or hazardous wastes impacts would be anticipated.

Federal Aviation Administration

There would be no impacts expected from hazardous materials and hazardous waste from the FAA’s No Action Alternative because there would be no launch events from KLC.

4.1.6.2 Alternative 1

4.1.6.2.1 Ground-Based Interceptors

Construction

Construction activities in support of GBI launch activities at KLC are generally discussed in section 2.3.1.1 and include GBI silo or launch pad and support facility construction as well as the IDT, COMSATCOM, TPS-X radar, mobile telemetry and C-band radar gravel pad construction; maintenance storage building and Launch Control Complex additions; addition to the existing Narrow Cape Lodge; construction of a new mancamp; and utilities/communication installation. Construction activities would be centralized to the greatest extent possible at the selected project site and on specific construction laydown areas and access roads. Hazardous materials and waste management would be performed in accordance with ongoing KLC procedures, as described in the KLC User’s Manual (Alaska Aerospace Development Corporation, 2001) as well as applicable federal, state and local regulations.
The construction of the GBI launch support infrastructure would use small quantities of hazardous materials, which would result in the generation of some hazardous and nonhazardous wastes (Halliburton NUS Environmental Corporation, 1993). The hazardous materials that are expected to be used are common to construction activities and may include diesel fuel, anti-freeze, hydraulic fluid, lubricating oils, welding gases, and small amounts of paints, thinners, and adhesives.

Substantial impacts to the environment are not expected from the presence of potentially hazardous materials and the generation of wastes during the GBI construction activities. Best practices, lessons learned and expectations indicated in the interim guidance DoD 5000.2R would be incorporated into design and construction plans. The following hazardous materials management techniques may be used during the construction period to minimize (1) the amount of hazardous materials stored, (2) the threat of their accidental and unplanned release into the environment, and (3) the quantity of hazardous waste generated.

- Structures may be prefabricated by manufacturers and shipped for final assembly at the site using bolts to minimize the need for welding, painting, and other activities involving hazardous materials.
- No underground tanks exist at KLC and none would be installed as a result of this activity. Diesel fuel would be stored in ASTs with secondary containment and inspected daily in accordance with the provisions of the KLC SPCC Plan (as appropriate). ASTs may be removed after tests are complete or put in standby condition at KLC to support future activities. Fueling would follow existing procedures to minimize the potential for fuel spills.
- Bulk hazardous materials [e.g., 210-liter (55-gallon) drums of anti-freeze, hydraulic fluid, compressed welding gases] would be stored in approved containers that meet National Fire Protection Association industrial fire protection codes and required containment systems.
- Spill response materials (e.g., sorbents, drain covers, mops, brooms, shovels, drum repair materials and tools, warning signs and tapes, and personal protective equipment) would be readily available for use in the event of an unplanned release.
- Storage of hazardous materials would be in protected and controlled areas designed to comply with site-specific SPCC plans.
- Hazardous materials would be inspected before accepting a shipment (e.g., to validate container integrity, expiration date, etc.).
- Hazardous materials would be purchased in appropriately sized containers (e.g., if the material is used by the can, it would be purchased by the can rather than in bulk-sized containers).
- Over-purchasing of hazardous materials would be avoided.
- Hazardous material containers would be appropriately labeled.
- At the completion of the construction period, unused amounts of hazardous materials would be the responsibility of the construction contractors and would be safely removed from the site.

Nonhazardous and hazardous waste generated during construction activities include construction debris, empty containers, spent solvents, waste oil and anti-freeze, spill cleanup
materials (if necessary), and lead-acid batteries from construction equipment. Hazardous waste would be containerized and properly disposed of by individual contractors in accordance with Alaska Administrative Code, Title 18 - Environmental Conservation, Chapter 16 and KLC requirements. No permitted hazardous waste treatment or disposal facilities exist on Kodiak Island; therefore, all hazardous waste would be transferred by licensed hazardous waste transporters to the mainland for appropriate treatment or disposal.

The volume of nonhazardous, construction generated waste is expected to be small based on past experience. Nonhazardous waste would be removed by individual contractors for appropriate disposal at the Kodiak Island Borough landfill or at a landfill on the Alaska mainland. The construction schedule for the facility is approximately 15 months, with approximately 100 individuals involved in the construction process. Buildings may be constructed of prefabricated metal resulting in relatively small volumes of non-recyclable construction waste. Debris resulting from site preparation such as tree stumps would be burned onsite, and soil excavated during construction activities would be stockpiled for later onsite use.

Operation

Pre-Launch Activities
Missile components would be transported to KLC for temporary storage, pre-launch assembly and checkout, and launch preparation. Like the target missiles, the GBI components would be shipped to KLC as finished products that required only final assembly onsite. The hazardous materials contained within the missiles include solid fuel for the rocket and fuel and oxidizer for the EKV’s Divert and Attitude Control System propellant system. No separate fueling would occur; therefore, the likelihood of release and environmental effect would be small.

The handling and use of hazardous and toxic materials at the launch site during and between launch operations would be limited. Potentially hazardous materials used for maintenance, grounds keeping, and housekeeping activities would normally consist of fuel (external to those preloaded into the missiles) required for emergency power and heat, various solvents and cleaners, paints and primers, adhesives, and lubricants. It is expected that no more than 4 liters (1 gallon) of each of the solvents, cleaners, paints, adhesives, and lubricants would be present at any one time (U.S. Department of the Air Force, 1994b), with no more than 38 liters (10 gallons) in total. Fuel for the emergency generators would be stored in dedicated ASTs with secondary containment. The ASTs would be routinely inspected. The hazardous material and waste management techniques described for construction would also be followed during pre-launch operations. Again, substantial impacts to the environment are not expected from the use of potentially hazardous materials and generation of wastes during launch operations.

Launch Activities
GBI launch activity considerations include the Launch Hazard Area, flight corridor clearance, missile launch, and missile impact.

Emergency response would be required in the event of a pre-launch or post-launch event which resulted in the partial destruction of a missile. Such an event could result in the rupture of a rocket engine and exposure of the solid fuel. In the event of such mishap, spillage of the propellants could occur. The incident would be handled as an explosive ordnance event, and remaining potentially hazardous materials would be regarded as hazardous waste for
management purposes. Removal and disposal of nonhazardous and hazardous waste from KLC would be in accordance with applicable state and federal requirements.

One piece of equipment used on the EKV consists of a klystron tube which contains small quantities of beryllium. Beryllium is listed on the Toxic Substance Control Act Inventory. If maintenance were required, a new tube would be brought onsite and the replaced tube would be returned to the manufacturer for repair.

*Post-Launch Activities*
Following test activities, the GBI facilities would be readied for the next use or placed in standby mode. Post-launch activities would generally occur as discussed under the No Action Alternative target launch operations.

**4.1.6.2.2 Targets**

*Construction*
Construction activities would include target access roads, target launch pad, Movable Missile Building, Missile Assembly Building, Motor Storage Building and access road, existing Narrow Cape Lodge expansion, new mancamp construction, and utilities/communications installation. Generation of potential hazardous waste (e.g., corrosion control coatings, adhesives, and sealants) would be minimal. Management of hazardous materials and hazardous waste would be performed in accordance with AADC requirements, and would not significantly impact existing KLC hazardous materials and hazardous waste management procedures.

*Operation*

*Pre-Launch Activities*
Potential target missiles are described in section 2.1.2. Pre-launch activities include transportation of target missiles to KLC, temporary storage, pre-launch assembly and checkout and preparation of the missiles for launch. Missiles would be transported to KLC as ready-to-use components and assembled onsite. The launch operator would be responsible for transporting the fuel in accordance with DOT requirements. Because of the sealed nature of this mode of transport, the likelihood of release and environmental effect is small. No separate fuel transportation, onsite storage, or fueling operations would be performed.

The handling and use of potentially hazardous materials at the launch site during and between launch operations would be limited. Hazardous materials used for maintenance, grounds keeping, and housekeeping activities would normally consist of various solvents and cleaners, paints and primers, adhesives, and lubricants. It is expected that no more than 4 liters (1 gallon) of each of these types of materials would be present at any one time (U.S. Department of the Air Force, 1994b), with no more than 38 liters (10 gallons) in total.

Onsite waste management practices would include:

- The containerization of waste to prevent discharges of waste or leachate
- The prevention of litter
Controlling access by wildlife or disease vectors
Keeping the premises free of solid waste
The use of best available management practices for the control and prevention of runoff and erosion

Launch Activities
During a normal launch there would be minimal to no hazardous materials or hazardous waste impacts. However, safety procedures would be followed.

Potentially hazardous substances such as hydrogen chloride, aluminum oxide, carbon monoxide, and oxides of nitrogen would be generated from combustion of the solid rocket propellant during launch or in the event of a launch failure or abort. For a nominal launch, propellant would burn to completion. Although unlikely, it is possible that a rocket’s flight could be terminated early. In the event of an on-pad or in-flight launch failure, solid propellant could be expected to scatter over a wide area. The missile debris would impact inside the Launch Hazard Area. In such an impact, the rocket would contain a varying level of propellant that would depend on the flight time. If scattered on the ground, potential pollutant concentrations downwind are expected to be less than with a normal launch, as the solid propellant would burn more slowly in the open air than in a rocket motor. There would be minimal to no impact to mission critical personnel or to the public from such an incident.

There is also the unlikely possibility that an errant missile could impact off target. Should an off-target impact occur, the Range Safety Manager would be notified immediately. The Range Safety Manager would in turn report the incident to the appropriate public officials and initiate appropriate emergency response actions. Emergency response actions would be in accordance with the KLC User’s Manual.

Post-Launch Activities
Small amounts of potentially hazardous and nonhazardous wastes are expected to be generated during launch operations. Wastes would be segregated as nonhazardous, hazardous, and possibly special wastes for collection and disposal.

Nonhazardous waste would be removed for appropriate disposal at the Kodiak Island Borough landfill or on the Alaska mainland. Removal and disposal of nonhazardous and hazardous waste from KLC would be done in accordance with applicable state and federal requirements.

Hazardous materials management would be performed in accordance with ongoing KLC procedures, as described in the KLC User’s Manual (Alaska Aerospace Development Corporation, 2001) and the Alaska Hazardous Waste Management Regulations (Alaska Administrative Code, Title 18, Environmental Conservation, Chapter 16). Hazardous waste management at KLC would be the responsibility of the generator. Hazardous wastes would be collected for disposal in accordance with applicable federal, State of Alaska, and DoD requirements.
Since no permitted hazardous waste treatment or disposal facilities exist on Kodiak Island, all hazardous waste would be shipped to the mainland for appropriate treatment or disposal. Only licensed hazardous waste transporters would be used to transport hazardous wastes off site.

Post-launch activities would involve the release of Launch Hazard Areas, cleanup, and transportation from KLC. Following test activities, the launch facilities would be readied for the next use or placed in standby mode. Specific restoration actions would be determined on a case-by-case basis in coordination with the procedures of KLC and the Alaska Department of Environmental Conservation.

4.1.6.2.3 In-Flight Interceptor Communications Data Terminal

Construction
Alternative 1 would require the construction of one IDT (among three alternative sites), one COMSATCOM (among four alternatives), and connecting roads. Construction would include a gravel pad, concrete pad, security fencing and utilities/communications installation. Generation of potential hazardous waste (e.g., corrosion control coatings, adhesives, and sealants) would be minimal. Management of hazardous materials and hazardous waste would be performed in accordance with AADC requirements, and would not significantly impact existing KLC hazardous materials and hazardous waste management procedures.

Operation
Operation of the IDT and COMSATCOMs would have little effect on hazardous waste and hazardous materials management. A 3,785-liter (1,000-gallon) AST would be used for diesel fuel for the backup generator.

4.1.6.2.4 Sensors

Construction
Alternative 1 would require several gravel pad areas out of seven alternate locations for mobile telemetry. An existing disturbed area would be utilized, and therefore potential impacts related to hazardous materials and hazardous waste would be minimal.

Operation
Operation of the sensors would have minimal direct or indirect, short- or long-term effect on hazardous materials and hazardous waste.

4.1.6.2.5 TPS-X Radar

The TPS-X construction and operation requirements and potential impacts to hazardous materials and hazardous waste management would be similar to that described above for the IDT. The location would be the same as those described for the potential IDT and COMSAT facilities, and the potential impacts would be similar.
4.1.6.3 Alternative 2

Alternative 2 is similar to Alternative 1, except that GBI and IDT construction and operation activities would not occur and sensor operation would support only target missile launches.

4.1.6.4 Alternative 3

Because Alternative 1 includes GBIs, targets, and all associated facilities, the construction and operation impacts for Alternative 3 would be as described for Alternative 1.

4.1.6.5 Cumulative Impacts

Adherence to the existing hazardous materials and waste management systems on KLC would preclude the potential accumulation of hazardous materials or waste. The range has implemented an emergency response procedure that would aid in the evaluation and cleanup of any potentially hazardous materials released. The types of hazardous materials used and waste generated would be similar to those currently used at KLC. It is not likely that the Proposed Action of up to five launches (GBI and/or target) in conjunction with other currently planned or anticipated launches at KLC would exceed nine launches per year, the level of activity analyzed in the KLC EA. The proposed launch of GBI or target missiles is not expected to substantially increase the volume of hazardous materials used, or hazardous waste generated, at KLC. Therefore, proposed activities would not be expected to result in cumulative hazardous materials and hazardous waste impacts.

4.1.6.6 Mitigation Measures

No hazardous materials/hazardous waste mitigation measures are proposed for the GMD ETR activities at KLC.

4.1.7 HEALTH AND SAFETY—KODIAK LAUNCH COMPLEX

Missile launches by their very nature involve some degree of risk and it is for this reason that DoD and AADC has specific launch and range safety policies and procedures to assure that any potential risk to the public and government assets (launch support facilities) are minimized. Potential issues related to health and safety would include the transportation of missile components, the reliability of components during handling/assembly and launch associated debris and emissions. Appendix B includes a detailed discussion of safety policies and regulations. Appendix C contains a discussion of flight test safety.

4.1.7.1 No Action Alternative

Missile Defense Agency

Under the No Action Alternative, KLC would continue to operate as a commercial launch facility and provide ongoing support to single Strategic Target System launches. The Strategic Target System launches would be managed within the nine launches previously analyzed in the KLC EA (Federal Aviation Administration, 1996). Potential health and safety risks from debris impact, toxic chemical dispersion (exhaust emissions), and noise would be associated with pre-launch, launch, and post-launch activities. Planning and execution of target launches would be in compliance with federal, state, and local health and safety requirements and regulations, as
well as DoD and KLC Safety Policy. Adherence to such requirements ensures that potential risk to the general public, workers, and the launch areas do not exceed acceptable limits. Therefore, no increase in potential risk to health and safety would be expected as a result of selecting this alternative.

Federal Aviation Administration
There would be no impacts expected to health and safety from the FAA’s No Action Alternative because there would be no launch events from KLC.

4.1.7.2 Alternative 1

4.1.7.2.1 Ground-Based Interceptors

Construction
Construction activities in support of GBI launch activities at KLC are generally discussed in section 2.3.1.1 and include GBI silo or launch pad and support facility construction as well as the IDT, COMSATCOM, TPS-X radar, mobile telemetry, and C-band radar gravel pad construction, maintenance storage building and Launch Control Complex additions, addition to the existing Narrow Cape Lodge, construction of a new mancamp and utilities/communication installation. Construction activities would be centralized to the greatest extent possible at the selected project site and on specific construction laydown areas and access roads. All new construction or structure modification would be accomplished using the same procedures that AADC used to construct the present KLC infrastructure.

Public access would be restricted in accordance with the KLC’s Interagency Land Management Agreement that encourages public access except in cases where safety is concerned or protection of structures is needed. A health and safety plan would be prepared by the contractor and submitted to KLC/AADC to ensure the health and safety of onsite workers. A formally trained individual would be appointed to act as safety officer. The appointed individual would be the point of contact on all problems involving job site safety. During performance of work, the contractor must comply with all provisions and procedures prescribed for the control and safety of construction team personnel and visitors to the job site. Compliance with regulations would ensure that construction or modification of facilities would not impact health and safety of workers or range personnel. No impact to public health and safety would be expected.

Operation

Pre-Launch Activities
Pre-launch activities would include transportation of boosters, liquid fuel, and liquid oxidizer tanks for the EKV and missile preparation, assembly, and integration testing. Missile components and support equipment would be transported to Kodiak Island by sea or air from Government storage depots or contractor facilities. The interceptor may arrive at Kodiak with the EKV attached or the booster may be shipped separately from the EKV. All components and equipment would be handled and shipped in accordance with applicable military, state, and DOT regulations. Missile components would be packaged in shipping containers designed according to Alaska, DOT, and military requirements for protection of missile components and reduction of fire/explosion or risk of hazardous materials release in the event of an accident. All containers would have proper placards.
Sections 3.1.11 and 4.1.11 provide detailed discussion on Kodiak Island and KLC established air, ocean, and ground transportation systems. The primary hazard related to the transportation of missile components would be the potential for an accident involving the transport vehicle and a resulting explosion/fire of solid fuel motors and/or small explosive actuation devices (used in missile control and Flight Termination System). Operations involving the transport of explosives (including packaging and handling for movement) would require implementation of written procedures, which would be approved by KLC/AADC. Transport operations would be conducted under the supervision of an approved ordnance officer using explosive-certified personnel as necessary. Consequently, minimal health and safety impacts would be expected during transport of missile components.

Missile components transported by barge to the Port of Kodiak would likely arrive at the Lash Terminal. Lash is a privately owned terminal operated and serviced by Seaport Terminal Services, Inc. The Lash Terminal is licensed for explosive and hazardous materials handling. Lash is located south of the U.S. Coast Guard Station on the main road to KLC. Samson Tug & Barge routinely serves the Port of Kodiak from Seattle and Anchorage, and is familiar with aerospace transport requirements. A sealift accident during transport is considered highly unlikely. The potential for a major accident (sinking or total destruction of the seacraft) is minimal.

Once unloaded at Kodiak Island, missile components and support equipment could be shipped by tractor-trailer transport to KLC or barged to one of the following potential beach landing areas, Burton Ranch Beach (mancamp location), Boulder Beach (near Bear Paw Ranch), and Pasagshak Beach (near the Pasagshak Recreation Area). The Narrow Cape Lodge is an example of direct barge delivery to KLC. Temporary beach closure would be necessary, but would be considered routine and of short duration.

In each of the described cases, the accident probability presented reflects only the potential for an accident involving the transport vehicle. Only a small fraction of such accidents would affect missile propellants or explosives being transported due to the use of specialized shipping containers that protect the shipment. Consequently, minimal health and safety impacts would be expected during transport of missile components.

Appropriate safety measures as established by AADC would be instituted at the receiving terminals or airport. These safety measures include specified receiving and parking areas (for transport vehicles), establishment and enforcement of applicable ESQDs around receiving areas, restricting handling and transportation of missile components to specific and properly trained personnel, and using established and permitted transportation routes from the receiving terminal or airport to KLC.

Use of the Kodiak State Airport shared by commercial pilots and the U.S. Coast Guard would be required to support receipt and transportation of missile components and mission personnel (figure 4.1.7-1), just as has been done for previous rocket motor shipments to KLC. The ESQD would be 434 meters (1,425 feet) to any inhabited buildings and 260 meters (855 feet) to public traffic routes. A designated preferred parking/offloading area has been established at Kodiak Airport that would limit impact to the Buskin River State Recreation Site. An alternative parking/offloading area would be the location used during previous U.S. Air Force missile launches. In the event this alternate location is required, the ESQD would encroach on several campsites within Buskin River State Recreation Site and could require closure of the recreation site for one night while the boosters are at the airport. AADC would provide a 30-day advance
Kodiak Joint Tenant Airport and Buskin River State Recreation Site

Kodiak, Alaska

Figure 4.1.7-1

EXPLANATION

- State Park Property
- Restroom
- Picnic Shelter
- Campsite
- Fee Station
- Visitors Center

- Class 1 Explosive, Division 1.1 Inhabited Building ESQD 434 meters (1,425 feet)
- Class 1 Explosive, Division 1.1 Public Transit ESQD 261 meters (855 feet)
- Class 1 Explosive, Division 1.1 Inhabited Building ESQD Alternate Off-loading Point 434 meters (1,425 feet)
- Class 1 Explosive, Division 1.1 Public Transit ESQD Alternate Off-loading Point 261 meters (855 feet)

notice to Alaska State Parks regarding the closure. Once the boosters have been removed from the area, the ESQD would no longer be in effect and the campsites would again be accessible.

There would be no effect on U.S. Coast Guard Air Station search and rescue operations. Handling and transportation of the missile components would stop, or move, to allow the Coast Guard to proceed in the event of a search and rescue operation, and would resume after the all clear is provided.

For analysis purposes, a quantity of 20,410 kilograms (45,000 pounds) of division 1.1 explosive was assumed. An inhabited building ESQD with a radius of 434 meters (1,425 feet) would be established. The public transportation route ESQD would be 261 meters (855 feet). If the propellant is determined to be Division 1.3 explosive (22,700 kilograms [50,000 pounds]) then the ESQDs would be reduced to 74.7 meters (245 feet) from inhabited buildings and 74.7 meters (245 feet) from public transportation routes. The ESQD is based on information provided in Inhabited Building and Public Traffic Route Distances, DoD 6055.9-STD, Ammunition and Explosives Safety Standards. The ESQD determination would be based on the equivalent explosive force of all propellant and pyrotechnic materials contained in the flight vehicle. Establishment of the ESQD zone represents DoD’s determination that areas outside the zone provide acceptable protection, and requires that areas inside the ESQD zone be cleared of non-mission-essential personnel for the entire period during which the explosives are present. The ESQD would keep unauthorized personnel and individuals at a safe distance until the boosters are unloaded and transported by truck to KLC. The transportation route would be in accordance with the permit application submitted to and approved by the State of Alaska Department of Transportation before shipment of missile components. Transport of missile components is not expected to be a hazard to private properties along the transportation route. The same ESQDs would be established and enforced while the missile components are at KLC.

Access to launch support structures and hazardous materials storage areas would be limited to KLC/mission essential personnel. All personnel associated with the Proposed Action would be properly trained in compliance with applicable health and safety procedures and guidelines. All pre-flight hazardous operations would be conducted in accordance with applicable and routine safety regulations and operations plans.

The solid propellant used in the GBI missiles is very stable in the absence of an ignition source. The boosters would be grounded to help protect against lightning and static electricity. Electrostatic discharge ignition of boosters has been associated with low atmospheric moisture levels. Based on the high-moisture atmospheric conditions in Kodiak, it is unlikely that an electrostatic discharge would occur. To prevent a premature activation of the igniters or the Flight Termination System, the boosters would not be armed until just before launch.

The boosters would be processed and prepared for launch in the same manner as previous and ongoing missile launches from KLC. The major system components (boosters, in-flight destruct package, range safety equipment, and missile instrumentation) would be assembled and tested in the Integration and Processing Facility. All preparation activities would be conducted in accordance with applicable safety regulations and operations plans.
